

COMLINEAR® CLC1606

1.3GHz Current Feedback Amplifier

FEATURES

- 1.2GHz -3dB bandwidth at G=2
- 3,300V/ μ s slew rate
- 0.01%/0.01° differential gain/phase error
- 7.5mA supply current
- 875MHz large signal bandwidth
- 120mA output current (easily drives three video loads)
- Fully specified at 5V and \pm 5V supplies
- CLC1606: Pb-free SOT23-5
- CLC1606: Pb-free SOIC-8

APPLICATIONS

- RGB video line drivers
- High definition video driver
- Video switchers and routers
- ADC buffer
- Active filters
- High-speed instrumentation
- Wide dynamic range IF amp

General Description

The COMLINEAR CLC1606 is a high-performance, current feedback amplifier with superior bandwidth and video specifications. The CLC1606 provides 1.3GHz unity gain bandwidth, \pm 0.1dB gain flatness to 150MHz, and provides 3,300V/ μ s slew rate exceeding the requirements of high-definition television (HDTV) and other multimedia applications. The COMLINEAR CLC1606 high-performance amplifier also provide ample output current to drive multiple video loads.

The COMLINEAR CLC1606 is designed to operate from \pm 5V or +5V supplies. It consumes only 7.5mA of supply current. The combination of high-speed and excellent video performance make the CLC1606 well suited for use in many general purpose, high-speed applications including standard definition and high definition video. Data communications applications benefit from the CLC1606's total harmonic distortion of -68dBc at 10MHz and fast settling time to 0.1%.

Typical Application - Driving Dual Video Loads

Ordering Information

Part Number	Package	Pb-Free	RoHS Compliant	Operating Temperature Range	Packaging Method
CLC1606IST5X	SOT23-5	Yes	Yes	-40°C to +85°C	Reel
CLC1606ISO8	SOIC-8	Yes	Yes	-40°C to +85°C	Rail
CLC1606ISO8X	SOIC-8	Yes	Yes	-40°C to +85°C	Reel

Moisture sensitivity level for all parts is MSL-1.

SOT23-5 Pin Configuration

SOT23-5 Pin Assignments

Pin No.	Pin Name	Description
1	OUT	Output
2	-V _S	Negative supply
3	+IN	Positive input
4	-IN	Negative input
5	+V _S	Positive supply

SOIC Pin Configuration

SOIC Pin Assignments

Pin No.	Pin Name	Description
1	NC	No connect
2	-IN1	Negative input, channel 1
3	+IN1	Positive input, channel 1
4	-V _S	Negative supply
5	NC	No connect
6	OUT	Output
7	+V _S	Positive supply
8	NC	No connect

Absolute Maximum Ratings

The safety of the device is not guaranteed when it is operated above the "Absolute Maximum Ratings". The device should not be operated at these "absolute" limits. Adhere to the "Recommended Operating Conditions" for proper device function. The information contained in the Electrical Characteristics tables and Typical Performance plots reflect the operating conditions noted on the tables and plots.

Parameter	Min	Max	Unit
Supply Voltage	0	14	V
Input Voltage Range	$-V_S - 0.5V$	$+V_S + 0.5V$	V
Continuous Output Current		120	mA

Reliability Information

Parameter	Min	Typ	Max	Unit
Junction Temperature			150	°C
Storage Temperature Range	-65		150	°C
Lead Temperature (Soldering, 10s)			260	°C
Package Thermal Resistance

General Information - Current Feedback Technology

Advantages of CFB Technology

The CLC1606 Family of amplifiers utilize current feedback (CFB) technology to achieve superior performance. The primary advantage of CFB technology is higher slew rate performance when compared to voltage feedback (VFB) architecture. High slew rate contributes directly to better large signal pulse response, full power bandwidth, and distortion.

CFB also alleviates the traditional trade-off between closed loop gain and usable bandwidth that is seen with a VFB amplifier. With CFB, the bandwidth is primarily determined by the value of the feedback resistor, R_f . By using optimum feedback resistor values, the bandwidth of a CFB amplifier remains nearly constant with different gain configurations.

When designing with CFB amplifiers always abide by these basic rules:

- Use the recommended feedback resistor value
- Do not use reactive (capacitors, diodes, inductors, etc.) elements in the direct feedback path
- Avoid stray or parasitic capacitance across feedback resistors
- Follow general high-speed amplifier layout guidelines
- Ensure proper precautions have been made for driving capacitive loads

Figure 1. Non-Inverting Gain Configuration with First Order Transfer Function

Figure 2. Inverting Gain Configuration with First Order Transfer Function

CFB Technology - Theory of Operation

Figure 1 shows a simple representation of a current feedback amplifier that is configured in the traditional non-inverting gain configuration.

Instead of having two high-impedance inputs similar to a VFB amplifier, the inputs of a CFB amplifier are connected across a unity gain buffer. This buffer has a high impedance input and a low impedance output. It can source or sink current (I_{err}) as needed to force the non-inverting input to track the value of V_{in} . The CFB architecture employs a high gain trans-impedance stage that senses I_{err} and drives the output to a value of $(Z_o(j\omega) * I_{err})$ volts. With the application of negative feedback, the amplifier will drive the output to a voltage in a manner which tries to drive I_{err} to zero. In practice, primarily due to limitations on the value of $Z_o(j\omega)$, I_{err} remains a small but finite value.

A closer look at the closed loop transfer function (Eq.1) shows the effect of the trans-impedance, $Z_o(j\omega)$ on the gain of the circuit. At low frequencies where $Z_o(j\omega)$ is very large with respect to R_f , the second term of the equation approaches unity, allowing R_f and R_g to set the gain. At higher frequencies, the value of $Z_o(j\omega)$ will roll off, and the effect of the secondary term will begin to dominate. The -3dB small signal parameter specifies the frequency where the value $Z_o(j\omega)$ equals the value of R_f causing the gain to drop by 0.707 of the value at DC.

For more information regarding current feedback amplifiers, visit www.cadeca.com for detailed application notes, such as AN-3: *The Ins and Outs of Current Feedback Amplifiers*.

Application Information

Basic Operation

Figures 3, 4, and 5 illustrate typical circuit configurations for non-inverting, inverting, and unity gain topologies for dual supply applications. They show the recommended bypass capacitor values and overall closed loop gain equations.

Figure 3. Typical Non-Inverting Gain Circuit

Figure 4. Typical Inverting Gain Circuit

Figure 5. Typical Unity Gain (G=1) Circuit

CFB amplifiers can be used in unity gain configurations. Do not use the traditional voltage follower circuit, where the output is tied directly to the inverting input. With a CFB amplifier, a feedback resistor of appropriate value must be used to prevent unstable behavior. Refer to figure 5 and Table 1. Although this seems cumbersome, it does allow a degree of freedom to adjust the passband characteristics.

Feedback Resistor Selection

One of the key design considerations when using a CFB amplifier is the selection of the feedback resistor, R_f . R_f is used in conjunction with R_g to set the gain in the traditional non-inverting and inverting circuit configurations. Refer to figures 3 and 4. As discussed in the Current Feedback Technology section, the value of the feedback resistor has a pronounced effect on the frequency response of the circuit.

Table 1, provides recommended R_f and associated R_g values for various gain settings. These values produce the optimum frequency response, maximum bandwidth with minimum peaking. Adjust these values to optimize performance for a specific application. The typical performance characteristics section includes plots that illustrate how the bandwidth is directly affected by the value of R_f at various gain settings.

Gain (V/V)	R_f (Ω)	R_g (Ω)	$\pm 0.1\text{dB BW}$ (MHz)	-3dB BW (MHz)
1	390	-	136	1300
2	270	270	150	1200
5	270	67.5	115	750

Table 1: Recommended R_f vs. Gain

In general, lowering the value of R_f from the recommended value will extend the bandwidth at the expense of additional high frequency gain peaking. This will cause increased overshoot and ringing in the pulse response characteristics. Reducing R_f too much will eventually cause oscillatory behavior.

Increasing the value of R_f will lower the bandwidth. Lowering the bandwidth creates a flatter frequency response and improves 0.1dB bandwidth performance. This is important in applications such as video. Further increase in R_f will cause premature gain rolloff and adversely affect gain flatness.

Driving Capacitive Loads

Increased phase delay at the output due to capacitive loading can cause ringing, peaking in the frequency response, and possible unstable behavior. Use a series resistance, R_S , between the amplifier and the load to help improve stability and settling performance. Refer to Figure 6.

Figure 6. Addition of R_S for Driving Capacitive Loads

Table 2 provides the recommended R_S for various capacitive loads. The recommended R_S values result in $\leq 0.5\text{dB}$ peaking in the frequency response. The Frequency Response vs. C_L plot, on page 5, illustrates the response of the CLC1606 Family.

C_L (pF)	R_S (Ω)	-3dB BW (MHz)
20	20	375
100	10	180
1000	3.3	58

Table 1: Recommended R_S vs. C_L

For a given load capacitance, adjust R_S to optimize the tradeoff between settling time and bandwidth. In general, reducing R_S will increase bandwidth at the expense of additional overshoot and ringing.

Parasitic Capacitance on the Inverting Input

Physical connections between components create unintentional or parasitic resistive, capacitive, and inductive elements.

Parasitic capacitance at the inverting input can be especially troublesome with high frequency amplifiers. A parasitic capacitance on this node will be in parallel with the gain setting resistor R_f . At high frequencies, its impedance can begin to raise the system gain by making R_f appear smaller.

In general, avoid adding any additional parasitic capacitance at this node. In addition, stray capacitance

across the R_f resistor can induce peaking and high frequency ringing. Refer to the **Layout Considerations** section for additional information regarding high speed layout techniques.

Overdrive Recovery

An overdrive condition is defined as the point when either one of the inputs or the output exceed their specified voltage range. Overdrive recovery is the time needed for the amplifier to return to its normal or linear operating point. The recovery time varies, based on whether the input or output is overdriven and by how much the range is exceeded. The CLC1606 Family will typically recover in less than 10ns from an overdrive condition. Figure 7 shows the CLC1606 in an overdriven condition.

Figure 7. Overdrive Recovery

Power Dissipation

Power dissipation should not be a factor when operating under the stated 1000 ohm load condition. However, applications with low impedance, DC coupled loads should be analyzed to ensure that maximum allowed junction temperature is not exceeded. Guidelines listed below can be used to verify that the particular application will not cause the device to operate beyond its intended operating range.

Maximum power levels are set by the absolute maximum junction rating of 150°C . To calculate the junction temperature, the package thermal resistance value Θ_{JA} (Θ_{JA}) is used along with the total die power dissipation.

$$T_{\text{Junction}} = T_{\text{Ambient}} + (\Theta_{JA} \times P_D)$$

Where T_{Ambient} is the temperature of the working environment.

In order to determine P_D , the power dissipated in the load needs to be subtracted from the total power delivered by the supplies.

$$P_D = P_{\text{supply}} - P_{\text{load}}$$

Supply power is calculated by the standard power equation.

$$P_{\text{supply}} = V_{\text{supply}} \times I_{\text{RMS supply}}$$

$$V_{\text{supply}} = V_{S+} - V_{S-}$$

Power delivered to a purely resistive load is:

$$P_{\text{load}} = ((V_{\text{LOAD}})_{\text{RMS}})^2 / R_{\text{load eff}}$$

The effective load resistor ($R_{\text{load eff}}$) will need to include the effect of the feedback network. For instance,

$R_{\text{load eff}}$ in figure 3 would be calculated as:

$$R_L \parallel (R_f + R_g)$$

These measurements are basic and are relatively easy to perform with standard lab equipment. For design purposes however, prior knowledge of actual signal levels and load impedance is needed to determine the dissipated power. Here, P_D can be found from

$$P_D = P_{\text{Quiescent}} + P_{\text{Dynamic}} - P_{\text{Load}}$$

Quiescent power can be derived from the specified I_S values along with known supply voltage, V_{Supply} . Load power can be calculated as above with the desired signal amplitudes using:

$$(V_{\text{LOAD}})_{\text{RMS}} = V_{\text{PEAK}} / \sqrt{2}$$

$$(I_{\text{LOAD}})_{\text{RMS}} = (V_{\text{LOAD}})_{\text{RMS}} / R_{\text{load eff}}$$

The dynamic power is focused primarily within the output stage driving the load. This value can be calculated as:

$$P_{\text{DYNAMIC}} = (V_{S+} - V_{\text{LOAD}})_{\text{RMS}} \times (I_{\text{LOAD}})_{\text{RMS}}$$

Assuming the load is referenced in the middle of the power rails or $V_{\text{supply}}/2$.

Figure 8 shows the maximum safe power dissipation in the package vs. the ambient temperature for the 8 and 14 lead SOIC packages.

Figure 8. Maximum Power Derating

Better thermal ratings can be achieved by maximizing PC board metallization at the package pins. However, be careful of stray capacitance on the input pins.

In addition, increased airflow across the package can also help to reduce the effective Θ_{JA} of the package.

In the event the outputs are momentarily shorted to a low impedance path, internal circuitry and output metallization are set to limit and handle up to 65mA of output current. However, extended duration under these conditions may not guarantee that the maximum junction temperature (+150°C) is not exceeded.

Layout Considerations

General layout and supply bypassing play major roles in high frequency performance. Exar has evaluation boards to use as a guide for high frequency layout and as aid in device testing and characterization. Follow the steps below as a basis for high frequency layout:

- Include 6.8μF and 0.1μF ceramic capacitors for power supply decoupling
- Place the 6.8μF capacitor within 0.75 inches of the power pin
- Place the 0.1μF capacitor within 0.1 inches of the power pin
- Remove the ground plane under and around the part, especially near the input and output pins to reduce parasitic capacitance
- Minimize all trace lengths to reduce series inductances

Refer to the evaluation board layouts below for more information.

Evaluation Board Information

The following evaluation boards are available to aid in the testing and layout of these devices:

Evaluation Board	Products
CEB002	CLC1606IST5X
CEB003	CLC1606ISO8X

Evaluation Board Schematics

Evaluation board schematics and layouts are shown in Figures 9-14. These evaluation boards are built for dual-supply operation. Follow these steps to use the board in a single-supply application:

1. Short -Vs to ground.
2. Use C3 and C4, if the -Vs pin of the amplifier is not directly connected to the ground plane.

Mechanical Dimensions

SOT23-5 Package

NOTES:

1. Dimensions and tolerances are as per ANSI Y14.5M-1982.
 2. Package surface to be matte finish VDI 11~13.
 3. Die is facing up for mold. Die is facing down for trim/form, ie. reverse trim/form.
 4. The footlength measuring is based on the gauge plane method.
- △ Dimension are exclusive of mold flash and gate burr.
 △ Dimension are exclusive of solder plating.

SOIC-8 Package

SOIC-8		
SYMBOL	MIN	MAX
A1	0.10	0.25
B	0.36	0.48
C	0.19	0.25
D	4.80	4.98
E	3.81	3.99
e	1.27 BSC	
H	5.80	6.20
h	0.25	0.5
L	0.41	1.27
A	1.37	1.73
θ ₁	0°	8°
X	0.55 ref	
θ ₂	7° BSC	

NOTE:

1. All dimensions are in millimeters.
2. Lead coplanarity should be 0 to 0.1mm (0.004") max.
3. Package surface finishing: VDI 24~27
4. All dimension excluding mold flashes.
5. The lead width, B to be determined at 0.1905mm from the lead tip.
