

Description

The SAM9M10 is a multimedia enabled mid-range ARM926-based embedded MPU running at 400MHz, combining user interfaces, video playback and connectivity. It includes hardware video decoder, LCD Controller, resistive touchscreen, camera interface, audio, Ethernet 10/100 and high speed USB and SDIO.

The hardware video decoder supports H.264, MPEG-4, MPEG-2, VC-1, H.263. The SAM9M10 also provides hardware image post-processing, such as image scaling, color conversion and image rotation.

The SAM9M10 supports the latest generation of DDR2 and NAND Flash memory interfaces for program and data storage. An internal 133 MHz multi-layer bus architecture associated with 37 DMA channels, a dual external bus interface and distributed memory including a 64-KByte SRAM which can be configured as a tightly coupled memory (TCM) sustains the high bandwidth required by the processor and the high speed peripherals.

The I/Os support 1.8V or 3.3V operation, which are independently configurable for the memory interface and peripheral I/Os. This feature completely eliminates the need for any external level shifters. In addition it supports 0.8 ball pitch package for low cost PCB manufacturing.

The SAM9M10 power management controller features efficient clock gating and a battery backup section minimizing power consumption in active and standby modes.

The SAM9M10 device is particularly well suited for media-rich displays and control panels in home and commercial buildings, POS terminals, entertainment systems, internet appliances and medical.

- Notes:
1. Refer to peripheral multiplexing tables in [Section 9.4 “Peripheral Signals Multiplexing on I/O Lines”](#) for these signals.
 2. When configured as an input, the NRST pin enables asynchronous reset of the device when asserted low. This allows connection of a simple push button on the NRST pin as a system-user reset.
 3. Programming of this pull-up resistor is performed independently for each I/O line through the PIO Controllers. After reset, all the I/O lines default as inputs with pull-up resistors enabled, except those which are multiplexed with the External Bus Interface signals that require to be enabled as Peripheral at reset. This is explicitly indicated in the column “Reset State” of the peripheral multiplexing tables.

6.2.3 Masters to Slaves Access

All the Masters can normally access all the Slaves. However, some paths do not make sense, such as allowing access from the Ethernet MAC to the internal peripherals. Thus, these paths are forbidden or simply not wired, and shown as “-” in the following tables.

The four DDR ports are connected differently according to the application device.

The user can disable the Video Decoder in the Video Mode Configuration Register (bit VDEC_SEL) in the Chip Configuration User Interface.

- When the Video Decoder is not enabled (VDEC_SEL=0), the ARM instruction and data are respectively connected to DDR Port 0 and DDR Port 1. The other masters share DDR Port 2 and DDR Port 3.
- When the Video Decoder is enabled (VDEC_SEL=1), DDR Port 0 is dedicated to the video controller, and DDR Port 1 to the LCD controller. The remaining masters share DDR Port 2 and DDR Port 3.

7. Memories

Figure 7-1. SAM9M10 Memory Mapping

7.1 Memory Mapping

A first level of address decoding is performed by the AHB Bus Matrix, i.e., the implementation of the Advanced High performance Bus (AHB) for its Master and Slave interfaces with additional features.

Decoding breaks up the 4 Gbytes of address space into 16 banks of 256 Mbytes. The banks 1 to 6 are directed to the EBI that associates these banks to the external chip selects NCS0 to NCS5.

The bank 7 is directed to the DDRSDRC0 that associates this bank to DDR_NCS chip select and so dedicated to the 4-port DDR2/ LPDDR controller.

The bank 0 is reserved for the addressing of the internal memories, and a second level of decoding provides 1 Mbyte of internal memory area. The bank 15 is reserved for the peripherals and provides access to the Advanced Peripheral Bus (APB).

Other areas are unused and performing an access within them provides an abort to the master requesting such an access.

7.2 Embedded Memories

7.2.1 Internal SRAM

The SAM9M10 product embeds a total of 64 Kbytes high-speed SRAM split in 4 blocks of 16 KBytes connected to one slave of the matrix. After reset and until the Remap Command is performed, the four SRAM blocks are contiguous and only accessible at address 0x00300000. After Remap, the SRAM also becomes available at address 0x0.

Figure 7-2. Internal SRAM Reset

The SAM9M10 device embeds two memory features. The processor Tightly Coupled Memory Interface (TCM) that allows the processor to access the memory up to processor speed (PCK) and the interface on the AHB side allowing masters to access the memory at AHB speed (MCK).

A wait state is necessary to access the TCM at 400 MHz. Setting the bit NWS_TCM in the bus Matrix TCM Configuration Register of the matrix inserts a wait state on the ITCM and DTCM accesses.

7.2.2 TCM Interface

On the processor side, this Internal SRAM can be allocated to two areas.

- Internal SRAM A is the ARM926EJ-S Instruction TCM. The user can map this SRAM block anywhere in the ARM926 instruction memory space using CP15 instructions and the TCR configuration register located in the Chip Configuration User Interface. This SRAM block is also accessible by the ARM926 Masters and by the AHB Masters through the AHB bus
- Internal SRAM B is the ARM926EJ-S Data TCM. The user can map this SRAM block anywhere in the ARM926 data memory space using CP15 instructions. This SRAM block is also accessible by the ARM926 Data Master and by the AHB Masters through the AHB bus.

- Internal SRAM C is only accessible by all the AHB Masters. After reset and until the Remap Command is performed, this SRAM block is accessible through the AHB bus at address 0x0030 0000 by all the AHB Masters. After Remap, this SRAM block also becomes accessible through the AHB bus at address 0x0 by the ARM926 Instruction and the ARM926 Data Masters.

Within the 64 Kbyte SRAM size available, the amount of memory assigned to each block is software programmable according to Table 7-1.

Table 7-1. ITCM and DTCM Memory Configuration

SRAM A ITCM size (KBytes) seen at 0x100000 through AHB	SRAM B DTCM size (KBytes) seen at 0x200000 through AHB	SRAM C (KBytes) seen at 0x300000 through AHB
0	0	64
0	64	0
32	32	0

7.2.3 Internal ROM

The SAM9M10 embeds an Internal ROM, which contains the bootrom and SAM-BA program.

At any time, the ROM is mapped at address 0x0040 0000. It is also accessible at address 0x0 (BMS =1) after the reset and before the Remap Command.

7.2.4 Boot Strategies

The system always boots at address 0x0. To ensure maximum boot possibilities the memory layout can be changed with two parameters.

REMAP allows the user to layout the internal SRAM bank to 0x0 to ease the development. This is done by software once the system has boot.

BMS allows the user to lay out to 0x0, when convenient, the ROM or an external memory. This is done by a hardware way at reset.

Note: All the memory blocks can always be seen at their specified base addresses that are not concerned by these parameters.

The SAM9M10 Bus Matrix manages a boot memory that depends on the level on the pin BMS at reset. The internal memory area mapped between address 0x0 and 0x000F FFFF is reserved to this effect.

If BMS is detected at 1, the boot memory is the embedded ROM.

If BMS is detected at 0, the boot memory is the memory connected on the Chip Select 0 of the External Bus Interface.

7.2.4.1 BMS = 1, boot on embedded ROM

The system boots on Boot Program.

- Boot on on-chip RC
- Enable the 32768 Hz oscillator

 - SDCard
 - NandFlash
 - EEPROM connected on TWI0

- SAM-BA Boot in case no valid program is detected in external NVM, supporting
 - Serial communication on a DBGU
 - USB Device HS Port

7.2.4.2 BMS = 0, boot on external memory

- Boot on on-chip RC
- Boot with the default configuration for the Static Memory Controller, byte select mode, 16-bit data bus, Read/Write controlled by Chip Select, allows boot on 16-bit non-volatile memory.

For optimization purpose, nothing else is done. To speed up the boot sequence user programmed software should perform a complete configuration:

- Enable the 32768 Hz oscillator if best accuracy needed
- Program the PMC (main oscillator enable or bypass mode)
- Program and Start the PLL
- Reprogram the SMC setup, cycle, hold, mode timings registers for EBI CS0 to adapt them to the new clock
- Switch the main clock to the new value

8. System Controller

The System Controller is a set of peripherals that allows handling of key elements of the system, such as power, resets, clocks, time, interrupts, watchdog, etc.

The System Controller User Interface also embeds the registers that configure the Matrix and a set of registers for the chip configuration. The chip configuration registers configure the EBI chip select assignment and voltage range for external memories.

8.1 System Controller Mapping

The System Controller's peripherals are all mapped within the highest 16 KBytes of address space, between addresses 0xFFFF E800 and 0xFFFF FFFF.

However, all the registers of the System Controller are mapped on the top of the address space. All the registers of the System Controller can be addressed from a single pointer by using the standard ARM instruction set, as the Load/Store instructions have an indexing mode of ± 4 KB.

[Figure 8-1 on page 30](#) shows the System Controller block diagram.

[Figure 7-1 on page 23](#) shows the mapping of the User Interfaces of the System Controller peripherals.

8.2 System Controller Block Diagram

Figure 8-1. SAM9M10 System Controller Block Diagram

8.3 Reset Controller

The Reset Controller is based on two Power-on-Reset cells, one on VDDBU and one on VDDCORE.

The Reset Controller is capable to return to the software the source of the last reset, either a general reset (VDDBU rising), a wake-up reset (VDDCORE rising), a software reset, a user reset or a watchdog reset.

The Reset Controller controls the internal resets of the system and the NRST pin output. It is capable to shape a reset signal for the external devices, simplifying to a minimum connection of a push-button on the NRST pin to implement a manual reset.

The configuration of the Reset Controller is saved as supplied on VDDBU.

8.4 Shut Down Controller

The Shut Down Controller is supplied on VDDBU and allows a software-controllable shut down of the system through the pin SHDN. An input change of the WKUP pin or an alarm releases the SHDN pin, and thus wakes up the system power supply.

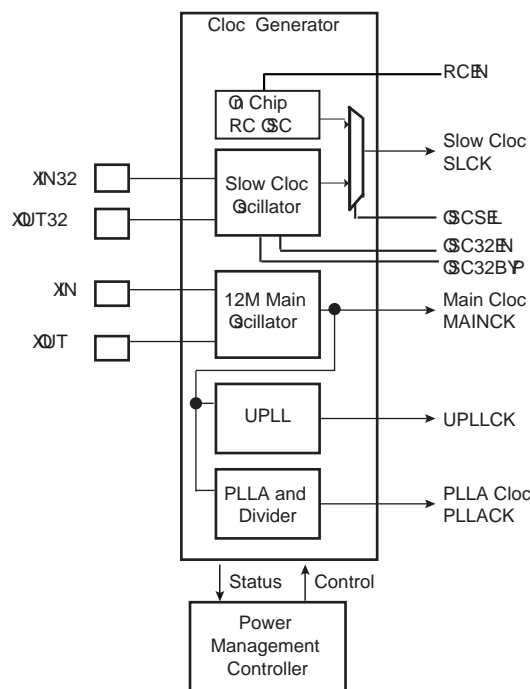

8.5 Clock Generator

The Clock Generator is made up of:

- One Low Power 32768 Hz Slow Clock Oscillator with bypass mode
- One Low-Power RC oscillator
- One 12 MHz Main Oscillator, which can be bypassed
- One 400 to 800 MHz programmable PLLA, capable to provide the clock MCK to the processor and to the peripherals. This PLL has an input divider to offer a wider range of output frequencies from the 12 MHz input, the only limitation being the lowest input frequency shall be higher or equal to 2 MHz.

The USB Device and Host HS Clocks are provided by a the dedicated UTMI PLL (UPLL) embedded in the UTMI macro.

Figure 8-2. Clock Generator Block Diagram

8.6 Slow Clock Selection

The SAM9M10 slow clock can be generated either by an external 32768Hz crystal or the on-chip RC oscillator. The 32768 Hz crystal oscillator can be bypassed, by setting the bit OSC32BYP, to accept an external slow clock on XIN32.

The internal RC oscillator and the 32768 Hz oscillator can be enabled by setting to 1 respectively RCEN bit and OSC32EN bit in the system controller user interface. OSCSEL command selects the slow clock source.

RCEN, OSC32EN, OSCSEL and OSC32BYP bits are located in the slow clock control register (SCKCR) located at address 0xFFFFFD50 in the backup part of the system controller and so are preserved while VDDBU is present.

Figure 8-3. Slow Clock

After a VDDBU power on reset, the default configuration is RCEN = 1, OSC32EN = 0 and OSCSEL = 0 allowing the system to start on the internal RC oscillator.

The programmer controls by software the slow clock switching and so must take precautions during the switching phase.

8.6.1 Switch from Internal RC Oscillator to the 32768 Hz Crystal

To switch from internal RC oscillator to the 32768 Hz crystal, the programmer must execute the following sequence:

- Switch the master clock to a source different from slow clock (PLLA or PLLB or Main Oscillator) through the Power Management Controller.
- Enable the 32768 Hz oscillator by setting the bit OSCEN to 1.
- Wait 32768 Hz startup time for clock stabilization (software loop).
- Switch from internal RC to 32768 Hz by setting the bit OSCSEL to 1.
- Wait 5 slow clock cycles for internal resynchronization.
- Disable the RC oscillator by setting the bit RCEN to 0.

8.6.2 Bypass the 32768 Hz Oscillator

The following step must be added to bypass the 32768 Hz Oscillator.

- An external clock must be connected on XIN32.
- Enable the bypass path OSC32BYP bit set to 1.
- Disable the 32768 Hz oscillator by setting the bit OSC32EN to 0.

8.6.3 Switch from 32768 Hz Crystal to the Internal RC Oscillator

The same procedure must be followed to switch from 32768 Hz crystal to the internal RC oscillator.

- Switch the master clock to a source different from slow clock (PLLA or PLLB or Main Oscillator).
- Enable the internal RC oscillator by setting the bit RCEN to 1.

- Wait internal RC Startup Time for clock stabilization (software loop).
- Switch from 32768 Hz oscillator to internal RC oscillator by setting the bit OSCSEL to 0.
- Wait 5 slow clock cycles for internal resynchronization.
- Disable the 32768Hz oscillator by setting the bit OSC32EN to 0.

8.7 Power Management Controller

The Power Management Controller provides all the clock signals to the system.

PMC input clocks:

- UPLLCK: From UTMI PLL
- PLLACK From PLLA
- SLCK: slow clock from OSC32K or internal RC OSC
- MAINCK: from 12 MHz external oscillator

PMC output clocks

- Processor Clock PCK
- Master Clock MCK, in particular to the Matrix and the memory interfaces. The divider can be 1,2,3 or 4
- DDR system clock equal to 2xMCK

Note: DDR system clock is not available when Master Clock (MCK) equals Processor Clock (PCK).

- USB Host EHCI High speed clock (UPLLCK)
- USB OHCI clocks (UHP48M and UHP12M)
- Independent peripheral clocks, typically at the frequency of MCK
- Two programmable clock outputs: PCK0 and PCK1

This allows the software control of five flexible operating modes:

- Normal Mode, processor and peripherals running at a programmable frequency
- Idle Mode, processor stopped waiting for an interrupt
- Slow Clock Mode, processor and peripherals running at low frequency
- Standby Mode, mix of Idle and Backup Mode, peripheral running at low frequency, processor stopped waiting for an interrupt
- Backup Mode, Main Power Supplies off, VDDBU powered by a battery

9.3 Peripheral Interrupts and Clock Control

9.3.1 System Interrupt

The System Interrupt in Source 1 is the wired-OR of the interrupt signals coming from:

- the DDR2/LPDDR Controller
- the Debug Unit
- the Periodic Interval Timer
- the Real-Time Timer
- the Real-Time Clock
- the Watchdog Timer
- the Reset Controller
- the Power Management Controller

The clock of these peripherals cannot be deactivated and Peripheral ID 1 can only be used within the Advanced Interrupt Controller.

9.3.2 External Interrupts

All external interrupt signals, i.e., the Fast Interrupt signal FIQ or the Interrupt signal IRQ, use a dedicated Peripheral ID. However, there is no clock control associated with these peripheral IDs.

9.4 Peripheral Signals Multiplexing on I/O Lines

The SAM9M10 features 5 PIO controllers, PIOA, PIOB, PIOC, PIOD and PIOE, which multiplexes the I/O lines of the peripheral set.

Each PIO Controller controls up to 32 lines. Each line can be assigned to one of two peripheral functions, A or B. The multiplexing tables in the following paragraphs define how the I/O lines of the peripherals A and B are multiplexed on the PIO Controllers. The two columns “Function” and “Comments” have been inserted in this table for the user’s own comments; they may be used to track how pins are defined in an application.

Note that some peripheral function which are output only, might be duplicated within the both tables.

The column “Reset State” indicates whether the PIO Line resets in I/O mode or in peripheral mode. If I/O is mentioned, the PIO Line resets in input with the pull-up enabled, so that the device is maintained in a static state as soon as the reset is released. As a result, the bit corresponding to the PIO Line in the register PIO_PSR (Peripheral Status Register) resets low.

If a signal name is mentioned in the “Reset State” column, the PIO Line is assigned to this function and the corresponding bit in PIO_PSR resets high. This is the case of pins controlling memories, in particular the address lines, which require the pin to be driven as soon as the reset is released. Note that the pull-up resistor is also enabled in this case.

To amend EMC, programmable delay has been inserted on PIO lines able to run at high speed.
