## Features

- 8.5V Supply Voltage
- Voltage Regulator for Stable Operating Conditions
- Microprocessor-controlled Via a Simple Two-wire Bus
- Two Selectable Addresses
- Gain-controlled RF Amplifier with Two Inputs, Selectable Via a Simple Two-wire Bus Control
- Balanced RF Amplifier Inputs
- Gain-controlled RF Mixer
- Four-pin Voltage-controlled Oscillator
- SAW Filter Driver With Differential Low-impedance Output
- AGC Voltage Generation for RF Section, Available at Charge-pump Output (Can Also Be Used to Control a PIN Diode Attenuator)
- Gain-controlled IF Amplifier
- Balanced IF Amplifier Inputs
- Selectable Gain-controlled IF Mixer
- Single-ended IF Output
- AGC Voltage Generation for IF Section, Available at Charge-pump Output
- Separate Differential Input for the IF AGC Block
- All AGC Time Constants are Adjustable
- AGC Thresholds Programmable Via a Simple Two-wire Bus
- Three AGC Charge Pump Currents Selectable (Zero, Low, High)
- Reference Oscillator
- Programmable 9-bit Reference Divider
- Programmable 15-bit Counter 1:2048 to 1:32767 Effectively
- Tri-state Phase Detector with Programmable Charge Pump
- Superior Phase-noise Performance
- Programmable Deactivation of Tuning Output
- Three Switching Outputs (Open Collector)
- Three D/A Converters (Resolution: 8 Bits)
- Lock Status Indication (Open Collector)

## 1. Description

The ATR2731 is a monolithically integrated Digital Audio Broadcasting one-chip front-end circuit manufactured using Atmel's advanced UHF5S technology. Its functionality covers a gain-controlled RF amplifier with two selectable RF inputs, a gain-controlled RF mixer, a VCO which provides the LO signal for the RF mixers, either directly or after passing a frequency divider, a SAW filter driver, an AGC block for the RF section, a gain-controlled IF amplifier, an IF mixer which can also be bypassed, an AGC block for the IF section, and a fractional-N frequency synthesizer. The frequency synthesizer controls the VCO to synthesize frequencies in the range of 70 MHz to 500 MHz in a $16-\mathrm{kHz}$ raster; within certain limits, the reference divider factor is fully programmable.

The lock status of the phase detector is indicated at a special output pin; three switching outputs can be addressed. A reference signal, generated by an on-chip reference oscillator, is available at an output pin. This reference signal is also used to generate the LO signal for the IF mixer, either by doubling the frequency or by using the reference frequency itself. Three D/A converters at a resolution of 8 bits provide a digitally controllable output voltage. The thresholds inside the AGC blocks can be digitally controlled by means of on-chip 4-bit D/A converters. All functions of this IC are controlled via a simple two-wire bus.

## 3. Functional Description

The ATR2731 represents a monolithically integrated front-end IC designed for applications in DAB receivers. It covers RF and IF signal processing, the PLL section and also supporting functions such as D/A converters or switching outputs.

Two RF input ports offer the possibility of handling various input signals such as a down-converted L-band signal or band II and band III RF signals. The high dynamic range of the RF inputs and the use of a gain-controlled amplifier and a gain-controlled mixer in the RF section offer the possibility of handling even strong RF input signals. The LO signal of the first mixer stage is derived from an on-chip VCO. The VCO frequency is either divided by two or directly fed to the mixer. In this way band II and band III can be covered easily.

In the IF section, it can be selected if the first IF signal is down-converted to a second, lower IF or if it is simply amplified to appear at the IF output. If the down-conversion option is chosen, it can be selected if the LO signal of the IF mixer is directly derived from the reference signal of the PLL, or if it is generated by doubling its frequency. The amplifiers in the IF section are gain-controlled in similar fashion to the RF section.

The RF and the IF part also contain AGC functional blocks which generate the AGC control voltages. The AGC thresholds can be defined by means of three on-chip 4-bit D/A converters.

The frequency of the VCO is locked to a reference frequency by an on-chip fractional-N PLL circuit which guarantees a superior phase-noise performance. The reference frequency is generated by an on-chip crystal oscillator which can also be overdriven by an external signal. Starting from a minimum value, the reference scaling factor is freely programmable.

Three switching outputs can be used for various switching tasks on the front-end board. Three 8 -bit D/A converters providing an output voltage between 0 V and 8.5 V are used to improve the tuning voltages of the tuned preselectors which are derived from the tuning voltage of the VCO.

## 4. RF Part

### 4.1 RF Gain-controlled Amplifier

In order to support two different channels, two identical input buffers with balanced inputs (RFA1, RFA2; RFB1, RFB2) are integrated. By setting the two-wire bus bits M0 and M1 (see "Simple Two-wire Bus Functions" on page 12), the active buffer can be selected. The buffers are followed by a gain-controlled amplifier whose output signal is fed to a gain-controlled mixer. The RF amplifiers are capable of handling input signals up to a typical power of -6 dBm without causing third-order intermodulation components stronger than -40 dBc .

### 4.2 RF Gain-controlled Mixer, VCO and LO Divider

The purpose of the RF mixer is to down-convert the incoming signal (band II, band III) to an IF frequency, which is typically 38.912 MHz . This IF signal is fed to an AGC voltage-generation block (which is described in the following section) and an output buffer stage. This driver stage has a low output impedance and is capable of driving a SAW filter directly via its differential output pins SAW1 and SAW2. The mixer's LO signal is generated by a balanced voltage-controlled oscillator whose frequency is stabilized by a fractional-N phase-locked loop. An example circuit of the VCO is shown in Figure 13-6 on page 24. The oscillator's tank is applied to the pins B1VC, C1VC, B2VC and C2VC as shown in the application circuit in Figure 12-1 on page 20. Before the VCO's signal is fed to the RF mixer, it has to pass an LO divider block where the VCO frequency is divided by either 1 or 2 . The setting of this divider is defined by means of the two-wire bus bits M0 and M1 as indicated in "Simple Two-wire Bus Functions" on page 12. This feature offers the possibility of covering both band II and band III by tuning the VCO frequency in the range between 200 MHz to 300 MHz .

### 4.3 RF AGC Voltage-generation Block

In this functional block, the output signal of the RF mixer is amplified, weakly band-pass filtered (transition range: X 8 MHz to X 80 MHz ), rectified and finally low-pass filtered. The voltage derived in this power-measurement process is compared to a voltage threshold (th1) which can be digitally controlled by an on-chip 4-bit D/A converter. The setting of this converter is defined by means of the two-wire bus bits TAi $(\mathrm{i}=1,2,3,4)$. Depending on the result of this comparison, a charge pump feeds a positive or negative current to pin CPRF in order to charge or discharge an external capacitor. The voltage of this external capacitor can be used to control the gain of an external preamplifier or attenuator stage. Furthermore, it is also used to generate the internal control voltages of an RF amplifier and mixer. For this purpose, the voltage at pin CPRF is compared to a voltage threshold (th2) which is also controlled by an on-chip 4-bit D/A converter whose setting is fixed by the two-wire bus bits TBi $(i=1,2,3,4)$.

The current of the RF AGC charge pump can be selected using the input pins WAGC and SLI (Table 4-1):

Table 4-1. Current of Charge Pump

| WAGC | SLI | Charge-pump Current $[\mu \mathrm{A}]$ |
| :--- | :---: | :---: |
| High | X | Off |
| Low | Low | 50 (slow mode) |
| Low | High | 190 (fast mode) |

The function can be seen in Figure 13-5 on page 23.

## 5. IF Part

### 5.1 IF Gain-controlled Amplifier

The signal applied to the balanced input pins IFIN1 and IFIN2 is amplified by a gain-controlled IF amplifier. The gain-control signal is generated by an IF AGC voltage-generation block which is described in the next section. To avoid offset problems, the output of the gain-controlled amplifier is fed to an amplifier/mixer combination by AC coupling.

### 5.2 IF Gain-controlled Amplifier/Mixer Combination

Depending on the setting of the two-wire bus bits M2, M3, the output signal of the gain-controlled IF amplifier is either mixed down to a lower, second IF or, after passing an output buffer stage, amplified before it appears at the single-ended output pin IFOUT. If the down-conversion option is chosen, this circuit still offers two possibilities concerning the synthesis of the IF mixer's LO signal. This LO signal is derived from the PLL's on-chip reference oscillator. By means of the two-wire bus bits M2 and M3, it can be decided whether the reference frequency is doubled before it is given to the mixer's LO port, or if it is used directly. The gain-control voltage of the amplifier/mixer combination is similar to the gain-controlled IF amplifier generated by an internal gain-control circuit.

### 5.3 IF AGC Voltage-generation Block

The purpose of this gain-control circuit in the IF part is to measure the power of the incoming signal at the balanced input pins IFAGCIN1 and IFAGCIN2, to compare it with a certain power level, and to generate a control voltage for the IF gain-controlled amplifiers and mixer. This architecture offers the possibility of ensuring an optimal use of the dynamic range of the A/D converter which transforms the output signal at pin IFOUT from the analog to the digital domain despite possible insertion losses of (anti-aliasing) filters which are arranged in front of the converter. Such a constellation is indicated in the application circuit in Figure 12-1 on page 20.

The incoming signal at the balanced input pins IFAGC1 and IFAGC2 passes a power-measurement process similar to that described in "RF AGC Voltage-generation Block" on page 7. For flexibility reasons, no band-pass filtering is implemented. The voltage derived in this process is compared to a voltage threshold (th3) which is defined by an on-chip 4-bit D/A converter. The setting of this converter is defined by the two-wire bus bits TCi $(i=1,2,3,4)$. Depending on the result of this comparison, a charge pump feeds a positive or negative current to pin CPIF in order to charge or discharge an external capacitor. The current of this charge pump can be selected using the pins WAGC and SLI (Table 5-1):

Table 5-1. Current of Charge Pump

| WAGC | SLI | Charge-pump Current |
| :---: | :---: | :---: |
| High | X | Off |
| Low | Low | $50 \mu \mathrm{~A}$ (slow mode) |
| Low | High | $190 \mu \mathrm{~A}$ (fast mode) |

The function can be seen in Figure 13-6 on page 24.

## 6. PLL Part

The purpose of the PLL part is to perform a phase lock of the voltage-controlled RF oscillator to an on-chip crystal reference oscillator. This is achieved by means of a special phase-noise-shaping technique based on the fractional-N principle. It concentrates the phase detector's phase-noise contribution to the spectrum of the controlled VCO at frequency positions where it does not impair the quality of the received DAB signal. A special property of the transmission technique used in DAB is that the phase-noise-weighting function measuring the influence of the LO's phase noise on the phase information of the coded signal in a DAB receiver has zeros; that is, if phase noise is concentrated in the position of such zeros as discrete lines, the DAB signal is not impaired as long as these lines do not exceed a set limit. For DAB mode I, this phase-noise- weighting function is shown in Figure 6-1.

Figure 6-1. Phase-noise-weighting Function

It is important to realize that this function shows zeros in all distances from the center line which are multiples of the carrier spacing. The technique of concentrating the phase noise in the positions of such zeros is patent protected.

### 6.1 Reference Oscillator

An on-chip crystal oscillator generates the reference signal which is fed to the reference divider. As already described in "IF Gain-controlled Amplifier/Mixer Combination" on page 8, the LO signal for the mixer in the IF section is derived. By applying a crystal to the pins OSCI and OSCO (Figure 13-2 on page 21), this oscillator generates a highly stable reference signal. If an external reference signal is available, the oscillator can be used as an input buffer. In such an application (Figure 13-3 on page 22), the reference signal has to be applied to the pin OSCI and the pin OSCO must be left open.

### 6.2 Reference Divider

Starting from a minimum value, the scaling factor $\mathrm{SF}_{\text {ref }}$ of the 9 -bit reference divider is freely programmable by means of the two-wire bus bits $r_{i}(i=0, \ldots, 8)$ according to
$S F_{\text {ref }}=\Sigma \Sigma_{i} \times 2^{i}$
If, for example, a frequency raster of 16 kHz is requested, the scaling factor of the reference divider has to be specified in such a way that the division process results in an output frequency which is four times higher than the desired frequency raster; that is, the comparison frequency of the phase detector equals four times the frequency raster. By changing the division ratio of the main divider from N to $\mathrm{N}+1$ in an appropriate way (fractional- N technique), this frequency raster is interpolated to deliver a frequency spacing of 16 kHz . So, effectively, a reference scaling divide factor
$\mathrm{SF}_{\text {refe,eff }}=4 \times \sum_{i} \times 2^{i}$
is achieved.
By setting the two-wire bus bit T , a test signal representing the divided input signal can be monitored at the switching output SWA.

## 7. Main Divider

The main divider consists of a fully programmable 13-bit divider which defines a division ratio N . The applied division ratio is either N or $\mathrm{N}+1$ according to the control of a special control unit. On average, the scaling factors $\mathrm{SF}=\mathrm{N}+\mathrm{k} / 4$ can be selected where $\mathrm{k}=0,1,2$ or 3 .

In this way, VCO frequencies $\mathrm{f}_{\mathrm{Vco}}=4 \times(\mathrm{N}+\mathrm{k} / 4) \times \mathrm{f}_{\text {ref }} /\left(4 \times \mathrm{SF}_{\text {ref }}\right)$ can be synthesized starting from a reference frequency $f_{\text {ref }}$. If we define $S F_{\text {eff }}=4 \times N+k$ and $S F_{\text {refeeff }}=4 \times S F_{\text {ref }}$ (from the previous section), then $f_{v c o}=S F_{\text {eff }} \times f_{\text {ref }} / \mathrm{SF}_{\text {refe,eff }}$, where $\mathrm{SF}_{\text {eff }}$ is defined by 15 bits.
In the following, this circuit is described in terms of $S F_{\text {eff }}$ and $\mathrm{SF}_{\text {ref,eff }} . \mathrm{SF}_{\text {eff }}$ has to be programmed via the two-wire bus interface. An effective scaling factor from 2048 to 32767 can be selected by means of the two-wire bus bits $n_{i}(i=0, \ldots, 14)$ according to

$$
S F_{\text {eff }}=\sum n_{i} \times 2^{i}
$$

By setting the two-wire bus bit T , a test signal representing the divided input signal can be monitored at the switching output SWC.

When the supply voltage is switched on, both the reference divider and the programmable divider are kept in RESET state until a complete scaling factor is written onto the chip. Changes in the setting of the programmable divider become active when the corresponding two-wire bus transmission is completed. An internal synchronization procedure ensures that such changes do not become active while the charge pump is sourcing or sinking current at its output pin. This behavior allows a smooth tuning of the output frequency without restricting the controlled VCO's frequency spectrum.

### 7.1 Phase Comparator and Charge Pump

The tri-state phase detector causes the charge pump to source or to sink current at the output pin PD depending on the phase relation of its input signals provided by the reference and the main divider respectively. Four different values of this current can be selected by means of the two-wire bus bits I50 and I100. By use of this option, changes of the loop characteristics due to the variation of the VCO gain as a function of the tuning voltage can be reduced. The charge-pump current can be switched off using the two-wire bus bit TRI. A change in the setting of the charge pump current becomes active when the corresponding two-wire bus transmission is completed. As described for the setting of the scaling factor of the programmable divider, an internal synchronization procedure ensures that such changes do not become active while the charge pump is sourcing or sinking current at its output pin. This behavior allows a change in the charge pump current without restricting the controlled VCO's frequency spectrum.
A high-gain amplifier (output pin: VD), which is implemented in order to construct a loop filter, as shown in the application circuit, can be switched off by means of the two-wire bus bit OS.
An internal lock detector checks if the phase difference of the input signals of the phase detector is smaller than approximately 250 ns in seven subsequent comparisons. If phase lock is detected, the open collector output pin PLCK is set to H (logical value). It should be noted that the output current of this pin must be limited by external circuitry as it is not limited internally. If the two-wire bus bit TRI is set to H , the lock detector function is deactivated and the logical value of the PLCK output is undefined.

### 7.2 Switching Outputs

Three switching outputs controlled by the two-wire bus bits SWA, SWB, and SWC can be used for any switching task on the front-end board. The currents of these outputs are not limited internally. They have to be limited by an external circuit.

### 7.3 D/A Converters

Three D/A converters, A, B, and C, offer the possibility of generating three output voltages at a resolution of 8 bits. These voltages appear at the output pins CAO, CBO, and CCO. The converters are controlled via the two-wire bus interface by means of the control bits CA0, ..., CA7, CB0, ..., CB7 and CC0, ..., CC7, respectively, as shown in Table 8-1 on page 12. The output voltages are defined as
$V_{C A O}=\frac{V_{M}}{128} \times \sum_{j=0}^{7} C A j \times 2^{j}$
$\mathrm{V}_{\text {CBO }}=\frac{\mathrm{V}_{\mathrm{M}}}{128} \times \sum_{\mathrm{j}=0}^{7} \mathrm{CBj} \times 2^{\mathrm{j}}$
$\mathrm{V}_{\mathrm{CCO}}=\frac{\mathrm{V}_{\mathrm{M}}}{128} \times \sum_{\mathrm{j}=0}^{7} \mathrm{CCj} \times 2^{j}$
where $\mathrm{VM}=4.25 \mathrm{~V}$ nominally. Due to the rail-to-rail outputs of these converters, almost the full voltage range from 0 V to 8.5 V can be used. A common application of these converters is the digital synthesis of control signals for the tuning of preselectors. The output pins CAO, CBO, and CCO must be blocked externally with capacitors ( 100 nF ) as shown in the application circuit (see Figure 12-1 on page 20).

## 8. Simple Two-wire Bus Interface

Via its two-wire bus interface, various functions can be controlled by a microprocessor. These functions are outlined in Table 8-1 on page 12, and in Section 8.1 "Simple Two-wire Bus Functions" on page 12. The programming information is stored in a set of internal registers. By means of the pin ADR, two different two-wire bus addresses can be selected, as described in "Electrical Characteristics" on page 16. Figure 8-1 on page 14 shows the two-wire bus timing parameters; Figure $8-2$ on page 14 shows a typical two-wire bus pulse diagram.

Table 8-1. $\quad$ Simple Two-wire Bus Instruction Codes

| Description | MSB |  |  |  |  |  |  | LSB |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Address | 1 | 1 | 0 | 0 | 0 | AS1 | 0 | 0 |

### 8.1 Simple Two-wire Bus Functions

| AS1 | Defines the two-wire bus address |
| :---: | :---: |
| $\mathrm{n}_{\mathrm{i}}$ | Effective scaling factor ( $\mathrm{SF}_{\text {eff }}$ ) of the main divider $\mathrm{SF}_{\text {eff }}=\sum_{i} \times 2^{i}$ |
| $\mathrm{r}_{\mathrm{i}}$ | Scaling factor ( $\mathrm{SF}_{\text {refe,fff }}$ ) of the reference divider $\mathrm{SF}_{\text {ref,eff }}=4 \times \mathrm{r}_{\mathrm{i}} 2^{i}$ |
| TAi | Define the setting of a 4-bit D/A converter controlling the threshold, th1, of the RF AGC to adjust the controlled output power |
| TBi | Define the setting of a 4-bit D/A converter controlling the threshold, th2, which determines the activation voltage for the internal RF AGC |
| TCi | Define the setting of a 4-bit D/A converter controlling the threshold, th3, of the IF AGC to adjust the output power |
| CAi, CBi, CCi | Define the setting of the three D/A converters $\mathrm{A}, \mathrm{B}$ and $\mathrm{C}(\mathrm{i}=0, \ldots, 7)$ |
| OS | OS = High switches off the tuning output |
| T | For $\mathrm{T}=$ High, reference signals describing the output frequencies of the reference divider and programmable divider are monitored at SWA (reference divider) and SWC (programmable divider). |
| TRI | TRI $=$ High switches off the charge pump |

I50 and I100 define the charge pump current:

Table 8-2. Current of Charge Pump

| I50 | I100 | Charge-pump Current <br> (nominal) $[\boldsymbol{\mu A}]$ |
| :---: | :---: | :---: |
| Low | Low | 50 |
| High | Low | 100 |
| Low | High | 150 |
| High | High | 200 |

Mi defines the operation mode:

Table 8-3. Mode Selection

| M3 | M2 | M1 | M0 | Mode |
| :---: | :---: | :---: | :---: | :---: |
| Low | Low | $X$ | $X$ | $\mathrm{f}_{\text {LO,IFMIX }}=\mathrm{f}_{\text {ref }}$ |
| Low | High | X | X | $\mathrm{f}_{\text {LO,IFMIX }}=2 \times \mathrm{f}_{\text {ref }}$ |
| High | High | X | X | IF mixer switched off |
| X | X | Low | Low | RF mixer A active, $\mathrm{f}_{\text {LO,RFMIX }}=\mathrm{f}_{\text {VCO }}$ |
| X | X | High | Low | RF mixer B active, $\mathrm{f}_{\text {LO,RFMIX }}=\mathrm{f}_{\text {VCO }}$ |
| X | X | High | High | RF mixer B active, $\mathrm{f}_{\text {LO,RFMIX }}=\mathrm{f}_{\text {VCO }} / 2$ |

Note: $\quad$ SW $\alpha=$ High switches on the output current $(\alpha=A, B, C)$

### 8.2 Simple Two-wire Bus Data Transfer

Format:
START - ADR - ACK - <instruction set> - STOP
The <instruction set> consists of a sequence of A bytes, B bytes, C bytes and D bytes each followed by ACK. A triplet of these bytes (A, B, C or D) must always be completed before a new triplet is started. If no new triplet is started the transmission can be finished before the current triplet is finished.

Examples:
START - ADR - ACK - DB1 - ACK - DB2 - ACK - DB3 - ACK - CB1 - ACK - CB2 - ACK - CB3 ACK - AB1 - ACK - AB2 - ACK - AB3 - ACK - BB1 - ACK - BB2 - ACK - BB3 - ACK - STOP

START - ADR - ACK - CB1 - ACK - CB2 - ACK - STOP
However:
START - ADR - ACK - DB1 - ACK - CB1 - ACK - STOP is not allowed.
Description:
START Start condition
STOP Stop condition
ACK Acknowledge
ADR Address byte
$\alpha B i \quad \alpha$ byte $i(\alpha=A, B, C, D ; i=1,2,3)$

### 8.3 Simple Two-wire Bus Timing

The values of the periods shown are specified in the table "Electrical Characteristics" on page 16. Please note, that according to the two-wire bus specification, the MSB of a byte is transmitted first, the LSB last.

Figure 8-1. Two-wire Bus Timing

Figure 8-2. Typical Pulse Diagram
START ADDRESS BYTE ACK A BYTE 1 ACK ABYTE 2

## 9. Absolute Maximum Ratings

| Parameters | Symbol | Min. | Max. | Unit |
| :---: | :---: | :---: | :---: | :---: |
| Supply voltage | $\mathrm{V}_{\text {S }}$ | -0.3 | +9.5 | V |
| Junction temperature | $\mathrm{T}_{\mathrm{j}}$ |  | 150 | ${ }^{\circ} \mathrm{C}$ |
| Storage temperature | $\mathrm{T}_{\text {stg }}$ | -40 | +150 | ${ }^{\circ} \mathrm{C}$ |
