

Features

- Precision synthesizer generates any clock-rate from 1 Hz to 177.5 MHz with jitter below 1ps
- Programmable digital PLL synchronize to any clock rate from 1 Hz (1 pps) to 750 MHz
- Input reference configurable as single ended LVCMOS (up to 177.5 MHz) or differential LVPECL (up to 750 MHz)
- Flexible two-stage architecture translates between arbitrary data rates, line coding rates and FEC rates
- Programmable Digital PLL loop filter: 30 mHz, 14 Hz, 28 Hz, 56 Hz, 112 Hz, 224 Hz, 448 Hz or 896 Hz
- Two LVCMOS outputs —from 1 Hz (1 pps) to 177.5 MHz
- Operates from a single crystal resonator or clock oscillator

Ordering Information

ZL30159GGG2 64 Pin LBGA* Trays
 *Pb Free Tin/Silver/Copper
 -40°C to +85°C

- Customer defined default device configuration, including input/output frequencies, is available via OTP(One Time Programmable) memory
- Dynamically configurable via SPI/I2C interface and volatile configuration registers

Applications

- General purpose clock rate translator
- GPS receiver clock synthesizer

Change Summary

Below are the changes made May 2014 issue to March 2015 issue.

| Page | Item | Change |
|------------|--|--|
| 1 | Added Features bullet | Included availability of customer defined default configurations |
| 12, 24, 24 | Updated section 4.0, 5.0 and added 5.1 | Updated to included the availability of Custom OTP configuration |
| 83 | 12.0, "Package Markings" | Added section 12 for package markings |

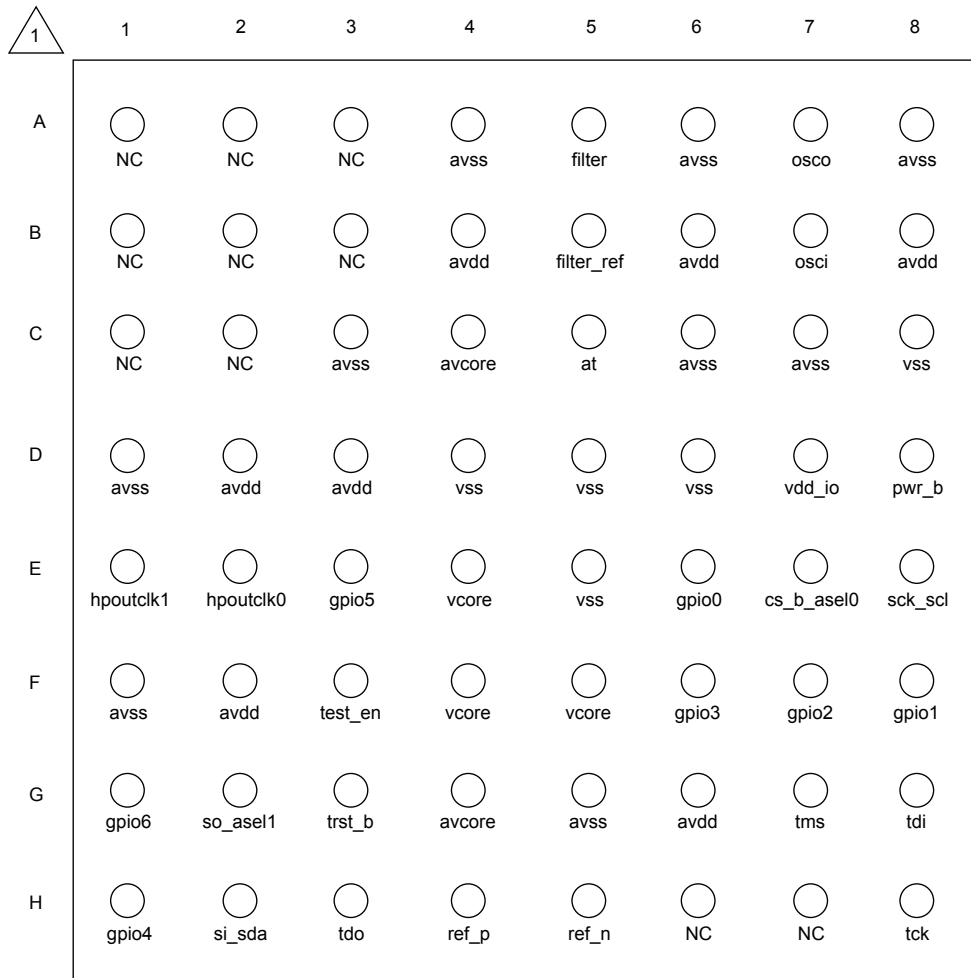

Below are the changes made from March 2013 issue to May 2014 issue.

| Page | Item | Change |
|-------------------|---|--|
| 36 and 65 | Register 0xC6: chip_revision | Updated chip revision register to include revH id number |
| 1, 11, 14, 15, 46 | 30MHz loop filter | Numerous reference to 30MHz loop filter were corrected to read 30mHz |
| 45 | Register 0x30 : dpll_ctrl | Changed bits [1:0] to reserved bits with default = 0b00 (DPLL Pull-in and Hold-in range settings available at register 0xED) |
| 57 | Register 0x86:0x88: synth_post_div_A | Corrected description of bits 17:16 |
| 59 | Register 0x89:0x8B: synth_post_div_B | Corrected description of bits 17:16 |
| 22 | 4.12, "Reset and Configuration Circuit" | Clarified power up conditions for gpio2 and gpio6 |
| 74 | DC Electrical Characteristics* - High Performance Outputs | Corrected the Sym for line 2 in the table |

Below are the changes made in March 2013 issue.

1.0 Pin Diagram

- A1 corner is identified by metallized markings.

2.0 Pin Description

All device inputs and output are LVCMOS unless it was specifically stated to be differential.

| Ball # | Name | I/O | Description |
|---------------------------|------------------------|-----|--|
| Input Reference | | | |
| H4 H5 | ref_p ref_n | I | <p>Input Reference. Input reference used for synchronization. The positive and negative pair of this input accept a differential input signal. The ref_p input terminal accept a CMOS input reference.</p> <p>Maximum frequency limit on single ended input is 177.5 MHz, and 750 MHz on differential input.</p> |
| Output Clocks | | | |
| E2 E1 | hpoutclk0 hpoutclk1 | O | <p>High Performance Output Clock 0 to 1. This output can be configured to provide any one of the single ended high performance clock outputs.</p> <p>Maximum frequency limit on single ended LVCMOS outputs is 177.5 MHz</p> |
| Control and Status | | | |
| D8 | pwr_b | I | <p>Power-on Reset. A logic low at this input resets the device. To ensure proper operation, the device must be reset after power-up. The pwr_b pin should be held low for at least 2 ms. This pin is internally pulled-up to V_{DD}. User can access device registers either 55 ms after pwr_b goes high, or after bit 7 in register at address 0x00 goes high which can be determined by polling address 0x00.</p> |

Table 1 - Pin Description

Table 1 - Pin Description (continued)

3.0 Application Example

The device integrates a digital PLL and a high-speed low-jitter clock synthesizer. The digital PLL locks to reference frequencies as low as 1 Hz while maintaining loop stability and while maintaining the device's low-jitter generation. The digital PLL ensures automatic stand-by mode on reference fail (holdover) preventing bit errors on the transmission links. The digital PLL implements loop filters with settings as low as 30 mHz to clean noisy references; or as high as 896 Hz to closely track less noisy references. The high-speed low-jitter clock synthesizer generates clocks with frequencies as high as 177.5 MHz with typical jitter performance below 1 ps RMS. The digital PLL plus high-speed synthesizer architecture allows the device to easily convert between SONET/SDH and Ethernet frequencies, with or without FEC scaling or line coding. Figure 2 shows an example application where ZL30159 is used to generate 25 MHz and 125 MHz (or any other two frequencies) from 1pps (1 Hz) input provided by GPS receiver. For applications where ZL30159 is synchronized to 1pps signal, ZL30159 loop bandwidth has to be 30 mHz.

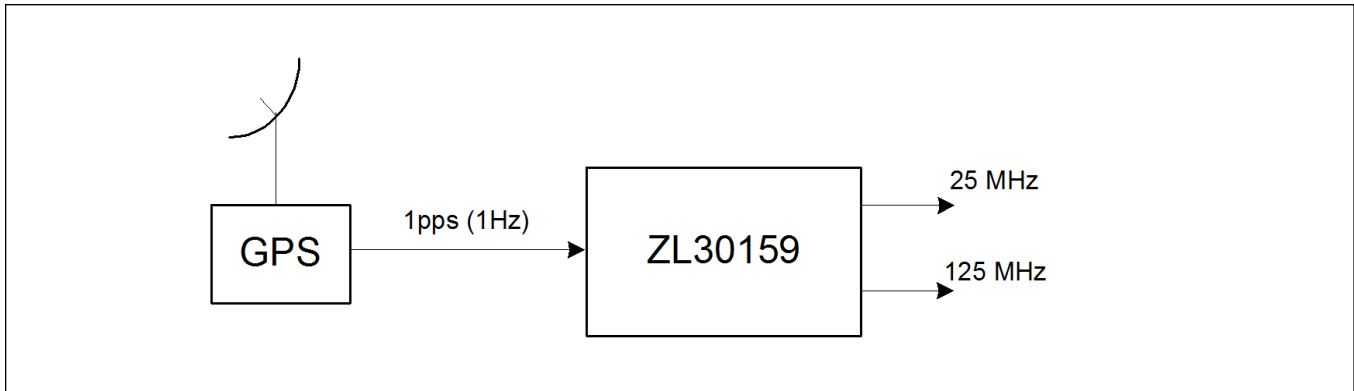

Figure 2 - Application Diagram

4.0 Functional Description

The functional block diagram of the device is shown in Figure 1. The ZL30159 is General Purpose Clock Rate Converter that can be configured by any of the following methods; power-up with its default configuration; power-up with a custom OTP (One Time Programmable) configuration; after power-up it can be dynamically configured via the SPI/I2C port. Configurations set via the SPI/I2C are volatile and will need to be rewritten if the device is reset or powered-down. The SPI/I2C port is also used to access the status registers. The ZL30159's detailed operation is described in the following sections.

4.1 Input Sources

The device has 2 input sources: one input reference (single ended or differential) and one oscillator clock source (oscillator or xtal).

The device master clock frequency is configured on reset via external voltage levels on GPIO[1:0] pins. The recommended frequency of the master clock is 24.576 MHz or 20 MHz.

The device synchronizes (locks) to any input reference which is a 1 Hz, 1 kHz multiple, or it synchronizes (locks) to any input reference which is an $(M/N \times 1 \text{ kHz})$ multiple (FEC rate converted) where M and N are 16 bits wide.

Input frequency is specified by programming four 16 bit registers: Base (B), Multiplier (K), M and N where input frequency is equal $B \times K \times M/N$. For example, to set the device to accept 1 Hz reference, the user will need to set B, K, M and N to 1. ZL30159 Evaluation Board GUI provides recommended B, K, M and N values for any required input reference frequency.

The device input reference frequency is programmed during initialization, change of input reference frequency can be supported if DPLL was forced in to Holdover mode before a frequency change.

The device accepts an input reference with maximum frequency of 177.5 MHz through single ended LVCMOS input (or 750 MHz frequency through differential inputs) and a minimum frequency of 1 Hz.

4.2 Input Reference Monitoring

The input reference is monitored by three reference monitor schemes. They indicate abnormal behavior of the reference signal, for example; drift from its nominal frequency or excessive jitter.

- **Loss of Signal Monitor (LOS):** LOS is an external signal, fed to one of ZL30159 pins. LOS is typically generated by a PHY device whose recovered clock is fed to ZL30159 reference input. PHY device will generate LOS signal when it cannot reliably extract the clock from the line. User can set one of GPIO pins as LOS input by programming corresponding GPIO register.
- **Coarse Frequency Monitor (CFM):** The CFM monitors input reference frequency for 1.25 ms so that it can quickly detect large changes in frequency. CFM limit for each input reference can be selected in corresponding `scm_cfm_limit_ref` registers with range from 0.1% to 50%. If the CFM limit is exceeded, then CFM failure is declared for corresponding reference.
- **Precise Frequency Monitor (PFM):** The PFM block measures the frequency accuracy of the reference over a 10 second interval. To ensure an accurate frequency measurement, the PFM measurement interval is re-initiated if phase or frequency irregularities are detected by the CFM. The PFM provides a level of hysteresis between the acceptance range and the rejection range to prevent a failure indication from toggling between valid and invalid for references that are on the edge of the acceptance range. PFM limit for each reference can be selected in `pfm_range` registers. When determining the frequency accuracy of the reference input, the PFM uses the external oscillator's output frequency (f_{ocsi}) as its point of reference. PFM limits can be set in `pfm_range` register at address 0xF7.
- **Single Cycle Monitor (SCM):** This detector measures rising to rising edge and falling to falling edge periods. If either of them exceeds predefined SCM limit then SCM failure is declared. SCM limit for each

input reference can be selected in corresponding scm_cfm_limit_ref registers with range from 0.1% to 50%. The limits are input frequency dependent. Please refer to the description in scm_cfm_limit_ref registers

- **Guard Soak Timer (GST):** Timer associated with the CFM and SCM modules to disqualify the reference input signal (see Table 2)

The monitor failure indicator is flagged in the status register and have associated mask bit, as follows:

- Reference Fail Mask: RefFailMask<3:0> in register at address 0x09: these bits mask the LOS, SCM, CFM, GST failure indicators and Ref Fail PFM Mask in register at address 0xF5.
- Holdover Mask for the reference: HOMask<3:0> in register at address 0x34, these bits mask the he LOS, SCM, CFM, GST failure indicators and DPLL Holdover Mask on PFM in register at address 0xF4 that are used to put device into auto-holdover on reference failure.
- MSB bit for GST and LSB bit for LOS

The single cycle and coarse monitor failure flags feed a timer (Guard Soak Timer) that disqualifies the reference input signal when the failures are present for more than the period of time defined in Table 2.

| Guard Soak Timer Control bits in control register | Time to disqualify a reference | Notes |
|---|--------------------------------|---------------|
| 00 | minimum delay possible | |
| 01 | 10 ms | |
| 10 | 50 ms | default value |
| 11 | 2.5 s | |

Table 2 - Guard Soak Time To Disqualify A Reference

The Guard Soak Timer that is used for the CFM and SCM modules has a built-in decay time hysteresis according to Table 3 (Timer to Qualify a reference) to prevent flickering of status bits at the threshold boundaries.

The Timer to Qualify a reference is a multiple of the Guard Soak Timer. Table 3 shows the multiplication factor to multiply the Guard Soak Timer to calculate the time to qualify a reference.

| Control bits to control the Timer to qualify a reference | Multiples of the Guard Soak Time to qualify a reference | Notes |
|--|---|---------------|
| 00 | 2 | |
| 01 | 4 | Default value |
| 10 | 16 | |
| 11 | 32 | |

Table 3 - Guard Soak Time To Qualify A Reference

When a GPIO pin is used as a reference fail indicator, it indicates a valid reference if:

- The SCM does not detect phase hits, nor complete loss of clock or RefFailMask<1> is at logic "0"
- The CFM does not detect phase irregularity or RefFailMask<2> is at logic "0"
- The Guard Soak Time is triggered or RefFailMask<3> is at logic "0"

4.2.1 DPLL General Characteristics

Pull-in Hold-in range

The DPLL supports pull-in/hold-in of +/-52 ppm, +/-130 ppm or +/-400 ppm or +/-3900 ppm.

DPLL bandwidth (jitter/wander transfer)

The DPLL supports the following first order filtering cut-off frequencies (30 mHz, 14 Hz, 28 Hz, 56 Hz, 112 Hz, 224 Hz, 448 Hz and 896 Hz), DPLL bandwidth is determined during initialization. When changing any parameter such as loop bandwidth, phase slope limit, input/output frequency etc, user should first put the device into the holdover or free run mode, program required changes, and then put the device back to the normal mode. Same procedure should be followed during the initialization phase.

The DPLL locks to an input reference and provides stable low jitter output clock if the selected loop bandwidth is less than 1/30th the input reference frequency. As an example, a 19.44 MHz reference could deploy a bandwidth up to 896 Hz, and a 1 kHz input reference would deploy a loop bandwidth of 14 Hz. For 8 kHz reference we recommend a maximum loop bandwidth of 56 Hz. 1 Hz input reference, requires loop bandwidth of 30 mHz. Such narrow loop bandwidth (30 mHz) requires very stable master crystal oscillator (TCXO or OCXO)

On the power up when the device is fed with low frequency reference such as 1 Hz with 30mHz loop bandwidth, the frequency lock will be achieved relatively fast. However, the phase lock will take longer time because the device needs to pull the phase of the output clock for up to half a second before the input and output get aligned. To speed up the phase lock time user should cycle device between normal and holdover mode three times as described below:

- On the power up the device is fed with 1pps reference
- Initialise the device by programming it via SPI/I2C bus and set it to normal mode
- Loop three times:
 - Wait for 50 seconds
 - Set the device to the holdover mode
 - Wait for 5 milliseconds
 - Set the device to the normal mode
- End loop

Jitter/Wander Generation

Jitter generation performance (detailed in Table 9 -, "Jitter Generation Specifications - HPOUT Outputs").

Wander generation of this device is applicable only when 30 mHz loop bandwidth is used. In this case wander generation is solely dependent on short term stability of master crystal oscillator. For wider loop bandwidths of 14 Hz or higher, wander generation of this device is negligible.

Phase Transients

The Microsemi device offers the following phase slope limiting options: 61 usec/sec, 7.5 usec/sec, 0.885 usec/sec or unlimited. If required phase slope limit is 0.885 usec/sec or 7.5 usec/sec, user should first set the device to unlimited phase slope and change it to required phase slope limit (0.885 usec/sec or 7.5 usec/sec) only after the device has achieved lock.

Holdover Stability

DPLL initial holdover accuracy is better than 50 ppb.

Input Tolerance Criteria

Input tolerance indicates that the device tolerates certain jitter, wander and phase transients at its input reference while maintaining outputs within an expected performance and without experiencing any alarms, or holdover conditions. Input tolerance is associated with input reference source characteristics and the standards associated with input reference type.

DPLL Monitoring

The DPLL provides lock and holdover indicators.

The lock time is dependent on employed loop bandwidth. The device has a lock time of less than 1 sec for all available DPLL loop bandwidth selections except 30 mHz.

The frequency lock time for 30 mHz loop bandwidth is up to 90 seconds. However, the phase lock is dependent on the input and output period—how far the output phase has to move to get phase aligned with the input phase. The slowest phase lock time will be for clock with maximum period (minimum frequency) which is 1 pps (1 Hz). For 1 pps, the phase lock time will be up to 20 minutes. To speed up the lock time for 1 pps clock, user should toggle the device though the holdover mode after 1 minute (normal mode - after 1 minute go to holdover mode and back to normal mode).

4.2.2 DPLL States

The device DPLL supports three states: Free-run, Normal (Locked) and Holdover. The Holdover and Free-run states are used to cope with reference impairments.

Each of these modes have a corresponding state in the internal State Machine described as follows:

Freerun State: the Freerun state is entered when synchronization to the reference is not required or is not possible. Typically this occurs immediately following system power-up. In the Freerun State, the device provides timing and synchronization signals which are based on the master clock frequency (supplied to osci pin) only, and are not synchronized to the reference input signals. The freerun accuracy of the output clock is equal to the accuracy of the master clock (osci). So if a ± 20 ppm freerun output clock is required, the master clock must also be ± 20 ppm.

Holdover State: the Holdover State is typically entered when input reference is temporarily disrupted. In the Holdover State, the device provides output clocks which are not locked to an external reference signal, but are based on storage techniques. The storage value is determined while the device is in Normal Mode and locked to an external reference signal. Initial holdover accuracy is a function of DPLL while holdover drift is reliant on the drift of the master clock (osci).

Normal State: the Normal State is entered when a valid reference clock is available for synchronization. In the Normal State the device provides output clocks which are synchronized to the input reference. From a reset condition - if a valid input reference is available - the device takes less than a second (lock time) to output signals which are synchronized (phase and frequency locked) to the reference input.

4.2.3 DPLL Rate Conversion Function and FEC Support

The DPLL supports rate conversion with a 16 bit forward divider and a 16 bit feedback divider.

The DPLL provides up scaling and down scaling functions.

The DPLL has the ability to switch from normal rate (before FEC is negotiated) to FEC rate and vice versa.

The DPLL supports simple rate conversion (i.e., take in 19.44 MHz and create 255/238 FEC SONET clock of 666.51 MHz), and supports double rate conversion (i.e., take in 19.44 MHz, create FEC 10 GbE clock of 644.5313, which is 66/64 rate converted 625 MHz, or create 690.5692 which is 255/238X66/64 rate converted 625 MHz)

The following is just an example of the frequencies that can be supported (many more frequencies can be supported):

- **GbE:**
 - 25 MHz
 - 125 MHz
- **XAUI (chip to chip interface, which is a common chassis to chassis interface):**
 - 156.25 MHz or x2 or x4 version
- **OC-192/STM-64:**
 - 155.52 MHz or x2 or x4 version
 - 155.52 MHz x 255/237 (standard EFEC for long reach) or x2 or x4 version
 - 155.52 MHz x 255/238 (standard GFEC for long reach) or x2 or x4 version
- **10 GbE:**
 - 156.25 MHz which is 125 MHz x 10/8 or x2 or x4 version
 - 155.52 MHz x 66/64 or x2 or x4 version
 - Long reach 10GE might require the following frequencies with simple rate conversion: (156.25 MHz x 255/237) and (156.25 MHz x 255/238).
 - The following frequencies with double rate conversion: (155.52 MHz x 66/64 x 255/237) or (155.52 MHz x 66/64 x 255/238) and (156.25 MHz x 66/64 x 255/238) or (156.25 MHz x 66/64 x 255/238). Also, user can use x2 or x4 version of the listed frequencies.
- Application Note ZLAN-267 explains how to generate the most common frequencies.

4.2.4 DPLL Input to Output And Output to Output Phase Alignment

Techniques offered for Phase Alignment

When the output clock is locked to a jitter free and wander free input clock, input to output latency is expected to have a typical error of 0 nsec.

The coarse and fine phase adjustments allow for input to output and output to output latency corrections to compensate for PCB load delay, as detailed in 4.6, "Output Drivers".

4.3 Frequency Synthesis Engine

The device frequency synthesis engine is comprised of a hardware DCO and an analog jitter filtering APLL with built-in digital jitter attenuation scheme. The ultra low jitter frequency synthesis engine can generate output clocks which meet the jitter generation requirements detailed in Table 9 -, "Jitter Generation Specifications - HPOUT Outputs".

The frequency synthesis engine's APLL requires an external RC loop filter as described in section 4.13

The frequency synthesis engines can generate any clock which is $(M/N \times 1 \text{ kHz})$ multiple (FEC rate converted clock). The M and N are 16 bits wide.

When the DPLL is locked to the input reference, the DCO external control can be used. The DCO external control allows for the calibration of the DCO center frequency to adjust for external system oscillator center frequency.

4.4 Dividers and Skew Management

The device has 2 independent dividers associated with frequency synthesis engine.

The divider engines can generate output clocks between 1 Hz and 177.5 MHz with 50% duty cycle.

The divider modules generating the single ended output clocks provides the ability to manage the phase skew of the output clock by a coarse step equal to the internal high speed clock period.

The single ended generated output clocks can be stopped either on rising or falling edge (programmed through serial interface or GPIO).

4.5 Output Multiplexer

Figure 3 shows the multiplexing configuration that is supported.

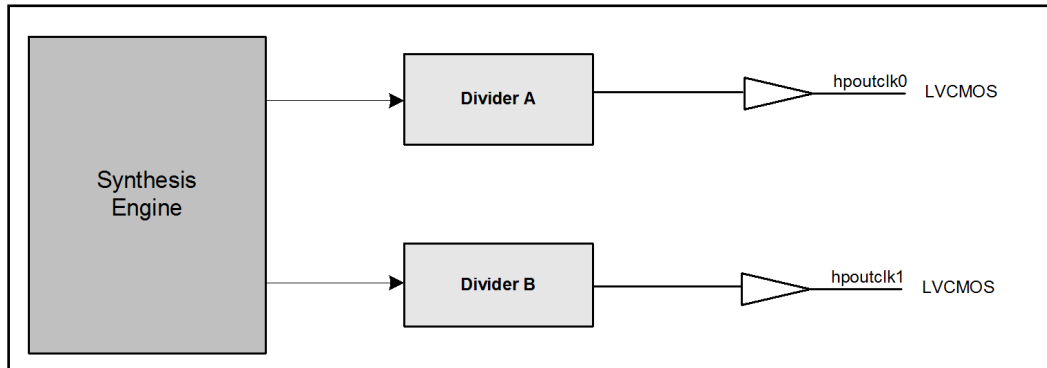

Figure 3 - Output Clocks Muxing Configuration

4.6 Output Drivers

The device has 2 high performance (HP) single ended (LVCMOS) outputs.

High Performance (HP) single ended driver (LVCMOS) supports the jitter specification detailed in Table 9 -, “Jitter Generation Specifications - HPOUT Outputs” and a maximum speed of 177.5 MHz.

High performance LVCMOS outputs (hpoutclkx) should be terminated at the source with $22\ \Omega$ resistor as shown in Figure 4.

Figure 4 - Terminating HP LVCMOS Outputs

4.7 Input Buffers

ZL30159 has one reference input ref_p/ref_n that can work as either single ended or differential. By default ref is single ended. This can be changed by programming ref_config register at address 0x0A.

Input frequency range for differential input is: 1 kHz to 750 MHz; for single ended input is: 1 kHz to 177.5 MHz.

Differential reference input need to be properly terminated and biased as shown in Figure 5 and Figure 6 for LVPECL and Figure 7 and Figure 8 for LVDS drivers. When terminating LVPECL signal, it is necessary either to adjust termination resistors for DC coupling or to AC couple the LVPECL driver because ZL30159 differential input have different common mode (bias) voltage than LVPECL receivers. Thevenin termination ($182\ \Omega$ and $68\ \Omega$ resistors) provide 50 ohm equivalent termination as well as biasing of the input buffer for DC coupled line. For AC

coupled line, Thevenin termination with $127\ \Omega$ and $82\ \Omega$ resistors should be used as shown in Figure 6. The value of the AC coupling capacitors will depend on the minimum reference clock frequency. The value of $10\ \text{nF}$ is good for input clock frequencies above $100\ \text{MHz}$. For lower clock frequencies capacitor values will have to be increased.

Terminations for DC and AC coupled LVDS line are shown in Figure 7 and Figure 8 respectively. Differential input biasing is provided by LVDS driver in case of DC coupling (Figure 7), whereas for AC coupling (Figure 8) biasing is generated by $12\ \text{k}\Omega$ and $8.2\ \text{k}\Omega$ resistors. In both cases, the line is terminated with $100\ \Omega$ resistor.

For single ended CMOS input, ref_n input needs to be connected to the ground as shown in Figure 9. The value of series termination resistor will depend on CMOS output driver but the most common values are $33\ \Omega$ and $22\ \Omega$.

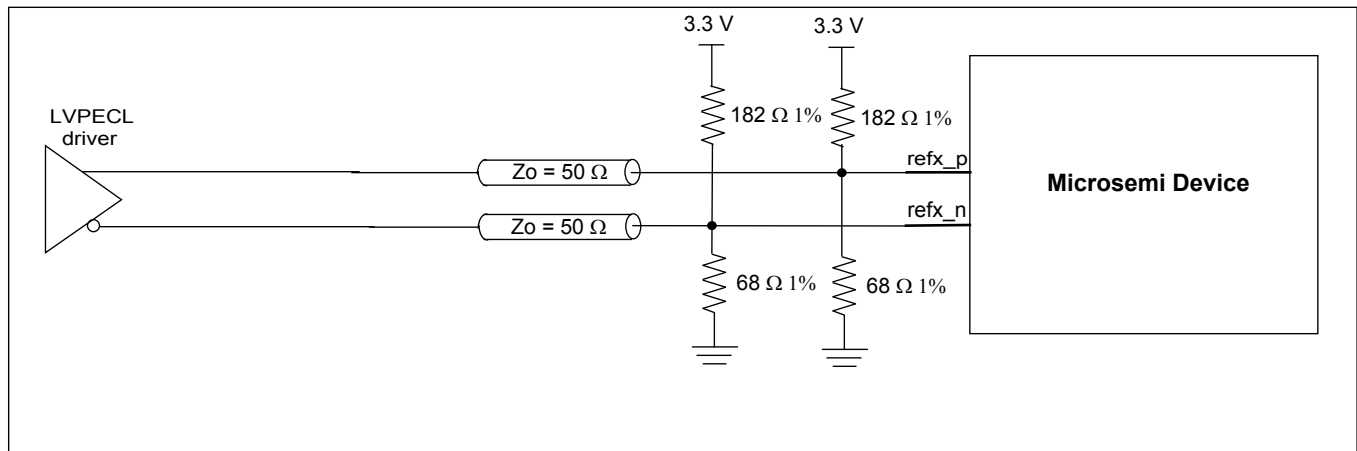

Figure 5 - Differential DC Coupled LVPECL Termination

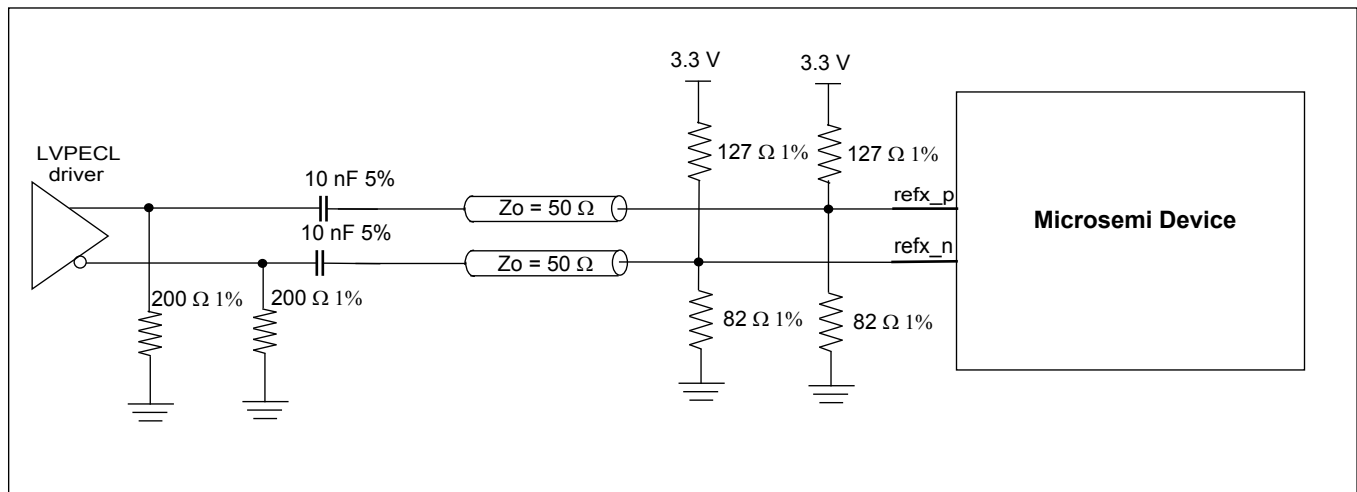

Figure 6 - Differential AC Coupled LVPECL Termination

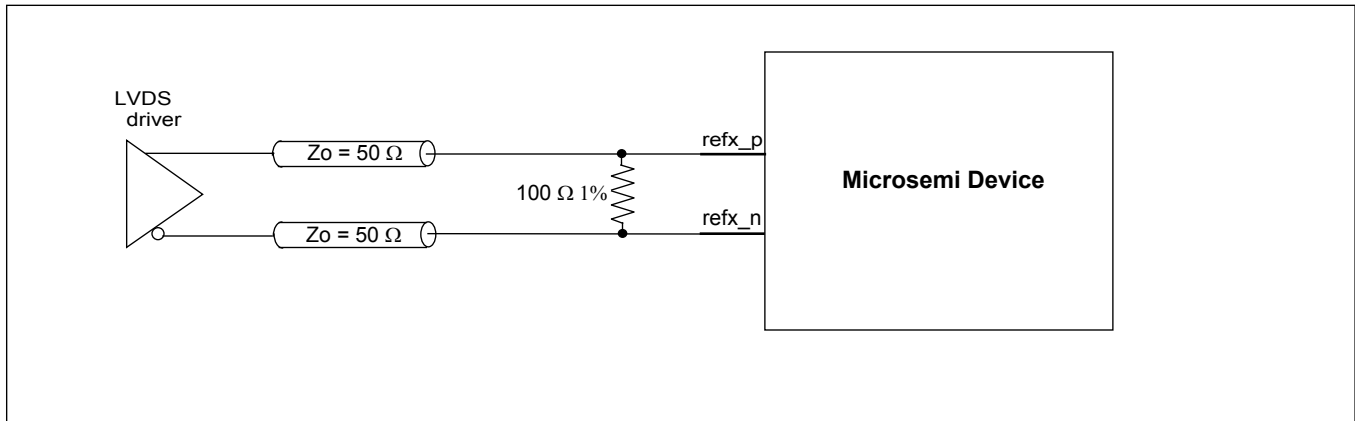

Figure 7 - Differential DC Coupled LVDS Termination

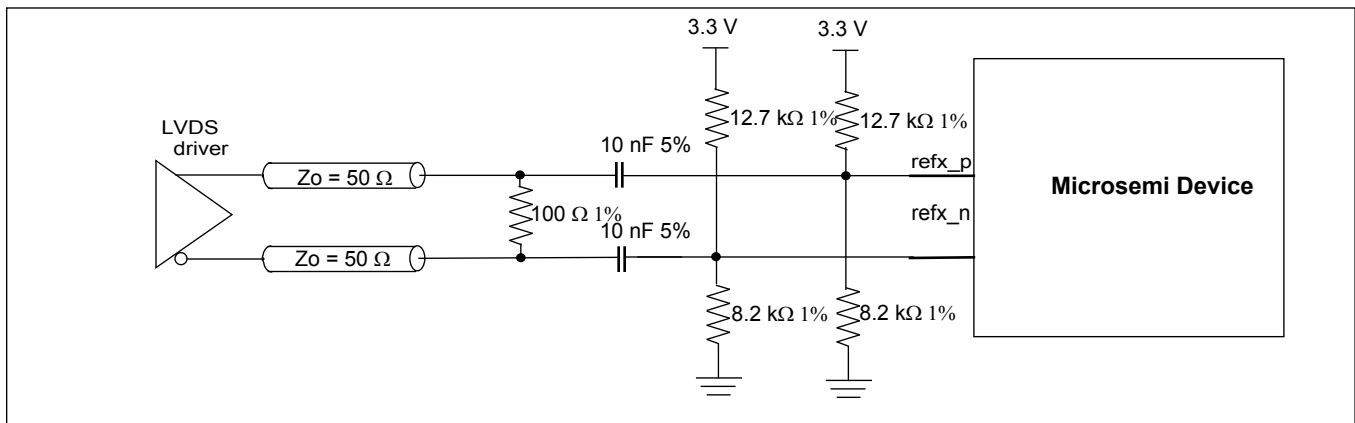

Figure 8 - Differential AC Coupled LVDS Termination

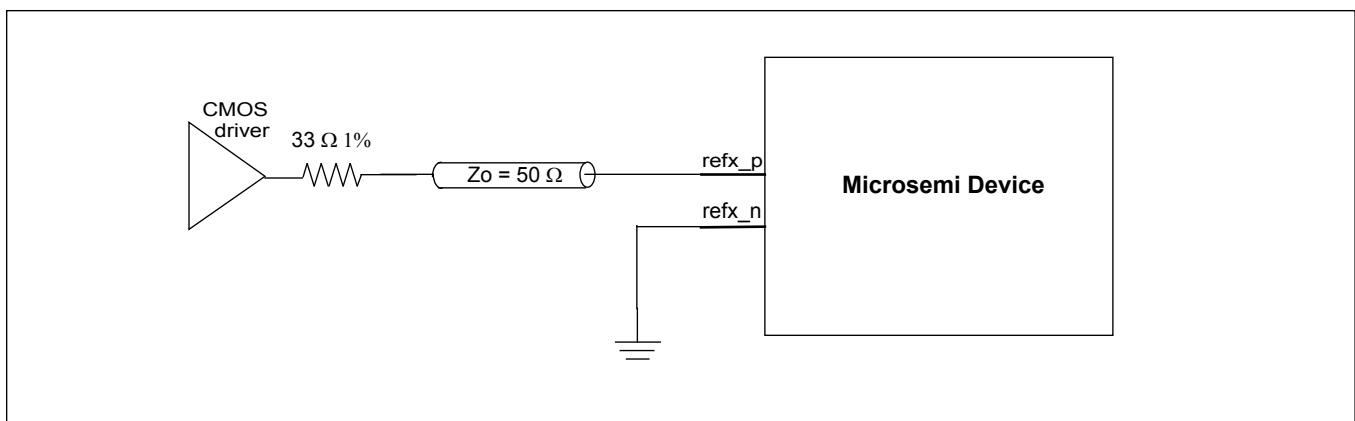

Figure 9 - Single Ended CMOS Termination

4.8 Master Clock Interface

The master oscillator determines the DPLL's free-run frequency accuracy and holdover stability. The reference monitor circuitry also uses this frequency as its point of reference (0 ppm) when making frequency measurements. The master clock interface was designed to accept either a free-running clock oscillator (XO) or a crystal (XTAL). Refer to application note ZLAN-68 for a list of recommended clock oscillators.

4.9 Clock Oscillator

When using a clock oscillator as the master timing source, connect the oscillator's output clock to the **osci** pin as shown in Figure 10. The connection to **osci** should be direct and not AC coupled. The **osco** pin must be left unconnected.

When using crystal resonator as the master timing source, connect crystal between **osci** and **osco** pins as shown in Figure 10. Crystal should have bias resistor of 1 M Ω and load capacitances C1 and C2. Value of load capacitances is dependent on crystal and should be as per crystal datasheet. Crystal should be a fundamental mode type -- not an overtone. See ZLAN-68 for crystal recommendation.

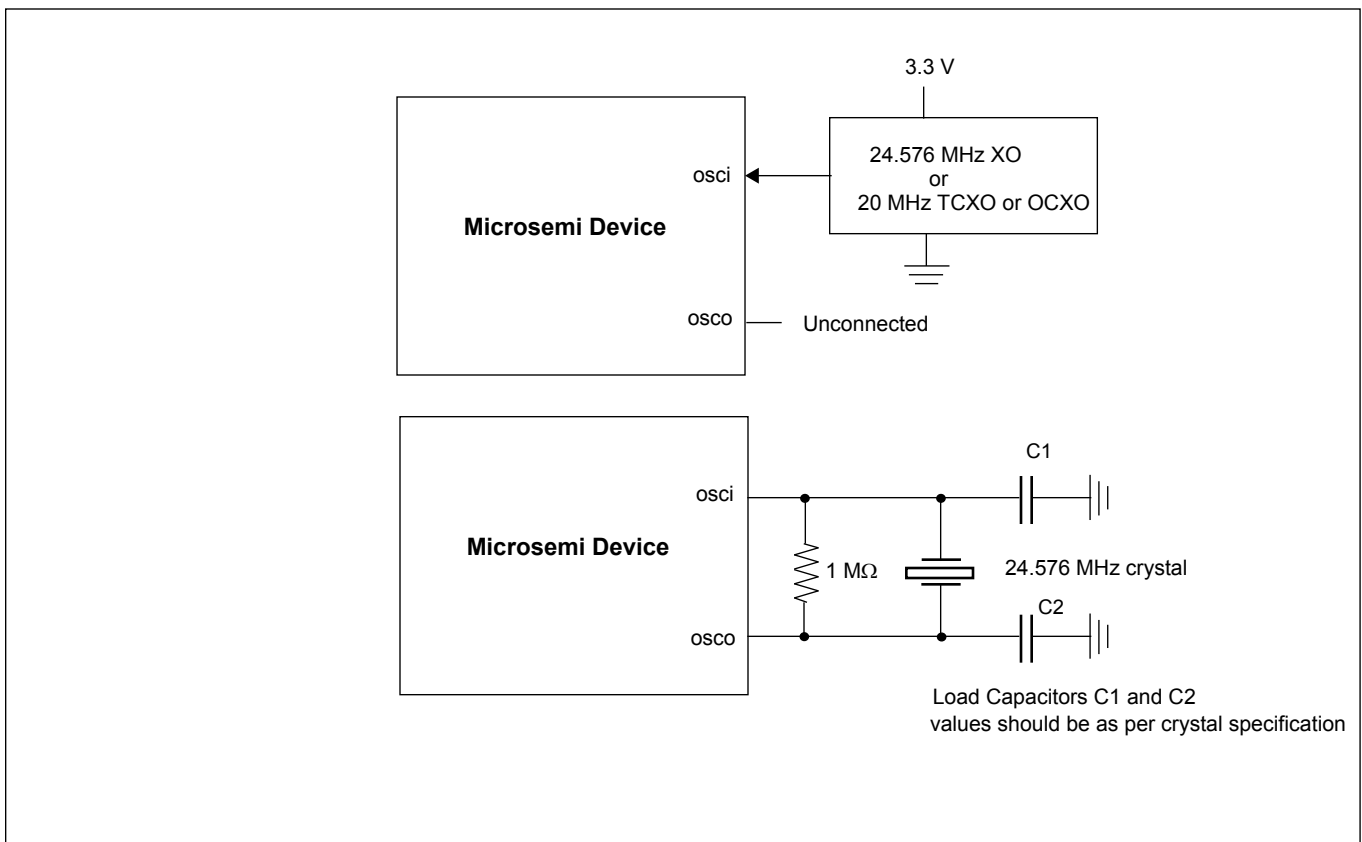

Figure 10 - Clock Oscillator Circuit

The device internal system clocks are generated off the device master clock input (Oscillator or a crystal employing an on-chip buffer/driver). The master clock selection is done at start-up using the available GPIO pins, right after **pwr_b** get de-asserted. GPIO[0,1] pins need to be held high for 55 ms after the de-assertion of **pwr_b**, after which time they can be released and used as any other GPIO. Alternatively, these pins can be pulled high with 1K Ω resistors.

| GPIO [1:0] | Master Clock Frequency |
|------------|------------------------|
| 00 | reserved |
| 01 | reserved |
| 10 | 20 MHz |
| 11 | 24.576 MHz |

Table 4 - Master Clock Frequency Selection

4.10 Power Up/Down Sequence

The 3.3 V power rail should be powered before or simultaneously with the 1.8 V power rail to prevent the risk of latch-up (latch-up occur when the 1.8 V supply exceeds the 3.3 V rail by more than 1.8 V).

The power-down sequence is less critical, however it should be performed in the reverse order to reduce transient currents that consume power.

4.11 Power Supply Filtering

Jitter levels on the output clocks may increase if the device is exposed to excessive noise on its power pins. For optimal jitter performance, the device should be isolated from noise on power planes connected to its 3.3 V and 1.8 V supply pins. For recommended common layout practices, refer to Microsemi Application Note ZLAN-230.

4.12 Reset and Configuration Circuit

To ensure proper operation, the device must be reset by holding the pwr_b pin low for at least 2 ms after power-up when 3.3V and 1.8V supplies are stable. Following reset, the device will operate under specified default settings.

The reset pin can be controlled with on-board system reset circuitry or by using a stand-alone power-up reset circuit as shown in Figure 11. This circuit provides approximately 2 ms of reset low time. The pwr_b input has Schmidt trigger properties to prevent level bouncing.

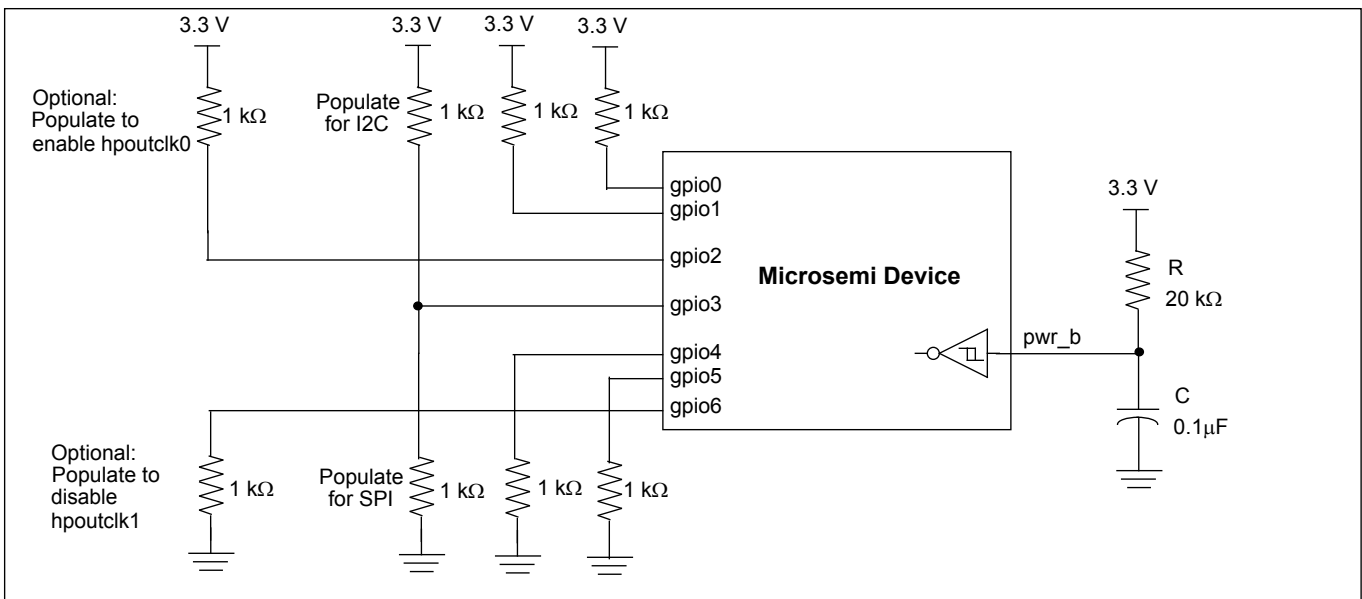

Figure 11 - Typical Power-Up Reset and Configuration Circuit with 24.576 MHz XO

General purpose pins gpio[0,1,3,4,5] are used to configure device on the power up. They have to be pulled up/down with 1 K Ω resistors as shown in Figure 11 or they can be pulsed low/high during the pwr_b low pulse and kept at the same level for at least 55 ms after pwr_b goes high. After 55 ms they can be released and used as general purpose I/O.

By default hpoutclk0 is disabled (gpio2 internal pull-down) and hpoutclk1 is enabled (gpio6 internal pull-up). During the prototype phase, a hardware designer can verify if the device is working properly even before the software driver is implemented just by pulling up gpio2 or gpio6 pin which enables hpoutclk0 output (generates 25 MHz by default) or hpclkout1 output (generates 125 MHz by default) respectively. This feature can also be used for systems where ZL30159 drives a master clock of an ethernet switch with embedded micro processor which needs 25 MHz (and/or 125 MHz) clock on the power up before it can initialize the other components on the board including ZL30159. The hpoutclk1 can be disabled at powerup by pulling down gpio6.

4.13 Ultra Low Jitter Synthesizer Filter Components and Recommended Layout

The APLL for the ultra low jitter synthesizer in the Microsemi device uses external components to help optimize its loop bandwidth. For optimal jitter performance, the following component values are recommended:

Figure 12 - APLL Filter Component Values

Recommended layout for loop filters is shown in Figure 13:

Figure 13 - Recommended Layout for Loop Filters

5.0 Configuration and Control

The ZL30159 configuration is composed of 253 x 8 bits. The configuration registers are assigned their values by any of the following three methods:

- 1) Default configuration
- 2) Custom OTP (One Time Programmable) configuration
- 3) SPI/I2C configuration

The SPI/I2C host interface allows field programmability of the device configuration registers. As an example, user might start the device at nominal SONET rate, then switch to an FEC rate once the link FEC rate is negotiated.

5.1 Custom OTP Configuration

At power-up the device sets its configuration registers to the user defined custom configuration values stored in its OTP (One Time Programmable). Custom configurations can be generated using Microsemi's Clockcenter GUI software (ZLS30CLKCTR). For custom configured devices contact your local Microsemi Field Applications Engineer or Sales Manager.

5.2 GPIO Configuration and Programmability

The device GPIO is mapped by the SPI/I2C programmability. The following is an example of control and status signals that can be supported:

- DPLL lock indicators
- DPLL holdover indicators
- Reference fail indicators
- Reference control or monitor
- Output clock enable (per output)
- Host Interrupt Output: flags changes of device status prompting the processor to read the enabled interrupt service registers (ISR).
- Output clock stop/start

The following table defines the function of the GPIO pin when configured as a control pin. Configuring the value in bit 7:0 in GPIO configuration registers enables the stated function.

| Value | Name | Description |
|-------------------------|---|--|
| Default | | |
| 0x00 | default | GPIO pin defined as an input. No function assigned. |
| Input References | | |
| 0x10 | Ref external LOS signal | Ref external Loss Of Signal (LOS) - indicator to DPLLs that Ref has failed. Internally in the DPLL this signal is used for reference monitor indicator, or holdover entering and for ISR generation. |
| DPLL | | |
| 0x20 | DPLL Time Interval Error (TIE) clear enable | This signal is OR-ed with the 'DPLL TIE clear enable' bit of the 'DPLL control' register. Functionality of this signal is explained in the 'DPLL control' register. |

| Value | Name | Description |
|--------------------------------------|--|--|
| Synthesizer Post Divider | | |
| 0x44 | Stop output clock from Synthesizer Post Divider A bit1 | This signal is OR-ed with the 'Synthesizer Post Divider A stop clock' bit1 in the 'Synthesizer Post Divider stop clock' register. Functionality of this signal is explained in above mentioned register. |
| 0x45 | Stop output clock from Synthesizer Post Divider A bit0 | Same description as above. |
| 0x46 | Stop output clock from Synthesizer Post Divider B bit1 | Same description as above. |
| 0x47 | Stop output clock from Synthesizer Post Divider B bit0 | Same description as above. |
| High Performance CMOS Outputs | | |
| 0x70 | Enable HPOUTCLK0 | This signal is OR-ed with the 'Enable HPOUTCLK0' bit in the 'High performance CMOS output enable' register. Functionality of this signal is explained in above mentioned register. |
| 0x72 | Enable HPOUTCLK1 | Same description as Enable HPOUTCLK0 |

The following table defines the function of the GPIO pin when configured as a status pin. Configuring the value in bit 7:0 in GPIO configuration registers enables the stated function.

| Value | Name | Description |
|-------------------------|--|---|
| Interrupt | | |
| 0x80 | Interrupt output signal | This bit will be high if the interrupt has been asserted. |
| Input References | | |
| 0x88 | Ref - Signal not present in last second | This bit will be high if Ref signal was not toggling in the last second. |
| 0x89 | Ref Single Cycle Measurement (SCM) failure | This bit will be set if Ref SCM indicator is active (see 'Ref SCM and CFM limits' register for SCM limits). |
| 0x8A | Ref Coarse Frequency Measurement (CFM) failure | This bit will be set if Ref CFM indicator is active (see 'Ref SCM and CFM limits' register for CFM limits). |
| 0x8B | Ref Guard Soak Timer (GST) indicator | Ref Guard Soak Timer (GST) indicator |
| 0x8C | Ref failure indicator | This bit will be set if either Ref external LOS signal is high, or Ref SCM, CFM or GST indicator is high, and appropriate mask bit in the 'Ref failure mask' register is set to 1 (not masked). |
| DPLL Filters | | |
| 0xA8 | DPLL Normal mode indicator | This bit will be set when the DPLL is in normal locking mode (not holdover, not freerun) |
| 0xA9 | DPLL holdover mode indicator | This bit will be set when the DPLL is in holdover mode |
| 0xAD | DPLL out of pull-in/hold-in range indication | This bit will be set when DPLL frequency is beyond pull-in/hold-in range limit, specified in the 'DPLL control' register |
| 0xAF | DPLL Lock Indication 0 | This bit will be set when DPLL phase error is less then 36us during 10s period. |

| Value | Name | Description |
|-------|------------------------|---|
| 0xB0 | DPLL Lock Indication 1 | This bit will be set when DPLL phase error is less then 1us during 1s period. |
| 0xB1 | DPLL Lock Indication 2 | This bit will be set when DPLL phase error is less then 10us during 1s period. |
| 0xB2 | DPLL Lock Indication 3 | This bit will be set when DPLL phase error is less then 10us during 10s period. |

5.3 Configuration Registers

This section refers to configuration registers that are set by the user to define device operation.

5.3.1 Input Reference Configuration and Programmability

The following is the set of parameters that are configurable:

- Input reference frequency as multiple of 1 kHz, and M/N ratio of the 1 kHz multiple or 1 Hz
- Input reference type: single ended or differential
- Holdover mode based on input reference single cycle monitor or coarse frequency monitor or guard soak timer

5.3.2 DPLL Configuration and Programmability

The following is the set of parameters that are configurable:

- DPLL input reference
- DPLL loop bandwidth

5.3.3 Synthesis Macro Configuration and Programmability

The following is the set of parameters that are configurable:

- Synthesis Macro locked to DPLL freerun or disabled
- Synthesis Macro mode M/N ratio or 1 kHz multiple
- Synthesis Macro high speed output clock, defined as a 1 kHz multiple and 1 kHz multiple with M/N ratio

5.3.4 Output Dividers and Skew Management Configuration and Programmability

The following is the set of parameters that are configurable:

- Post divider enable/disable
- Divider ratio
- Output delay value

5.3.5 Output Drivers configuration and Programmability

The following is the set of parameters that are configurable:

- Output driver Enable/Disable

5.4 State Control

The device has two main control modes of operation: un-managed mode and managed mode.

In un-managed mode of operation, the DPLL state (normal, freerun and holdover) is automatically set by the device internal state machine. It is based on availability of a valid reference.

In managed mode of operation, the DPLL state (normal, freerun and holdover) is manually set by the user.

The device allows for smooth transition from in and out of the two modes of operation. Hence if the DPLL was in managed mode and locked to the input reference and it was switched to un-managed mode of operation, then the state machine continues managing the device starting from being locked to the input reference and it will not force the device into holdover mode unless a change in conditions required such transition.

To facilitate monitoring and managing the device during managed mode of operation, and to facilitate monitoring the device during the un-managed mode, some control and status bits can be muxed into the GPIO pins. The following is a list for such control and monitor bits:

- DPLL state (2 control bits), Normal, holdover and freerun

- Reference monitoring (3 status bits)
- DPLL holdover indication (1 status bit)
- DPLL lock indication (1 status bit)

5.4.1 Un-managed Mode

In this mode, transitioning from one mode to the other is controlled by the device internal state machine.

The on-chip state machine monitors the device status bits, and based on the status information the state machine makes a decision to force holdover.

In the un-managed mode of operation, the device internal state machine manages the device operating states. The switch to holdover is based on the internal clock monitoring.

In un-managed mode of operation, the state machine only reacts to failure indicators and goes into auto-holdover under one of the following conditions if they are not masked with their corresponding mask bits:

- LOS detected a failure and HOMask<0> is at logic "1"
- SCM detected a failure and HOMask<1> is at logic "1"
- CFM detected a failure and HOMask<2> is at logic "1"
- The Guard Soak Time is triggered and HOMask<3> is at logic "1"
- PFM detected a failure and PFM_HOMask is set at logic "1"

The default conditions is HOMask<3:0> is "0111".

The default conditions for HOMask<3:0> (Register at address 0x34) is "0111" and for PFM_HOMask (register at address 0xF4) is "1".

In un-managed mode of operation, the state machine automatically recovers from auto-holdover when the conditions to enter auto-holdover are not present.

5.4.2 Managed Mode

The managed mode combines the functionality of the Holdover, Freerun and Normal states with automatic Holdover. In this mode, transitioning from one state to the other is controlled by an external controller.

The external controller monitors the device status bits. Based on the status information, the external controller makes a decision to force holdover. If the external controller sets the device to lock to a failed reference, the device stays in auto-holdover and only locks to that reference if it becomes valid.

The state machine only reacts to failure indicators and goes into auto-holdover under one of the following conditions if they are not masked with their corresponding mask bits:

- LOS detected a failure and HOMask<0> is at logic "1"
- SCM detected a failure and HOMask<1> is at logic "1"
- CFM detected a failure and HOMask<2> is at logic "1"
- The Guard Soak Time is triggered and HOMask<3> is at logic "1"
- PFM detected a failure and PFM_HOMask is set at logic "1"

The default conditions HOMask<3:0> (Register at address 0x34) is "0111" and for PFM_HOMask (register at address 0xF4) is "1".

The state machine automatically recovers from auto-holdover when the conditions to enter auto-holdover are not present.

Time critical state transitions for entry into auto-holdover and exit from auto-holdover are managed by the internal state machine.

6.0 Host Interface

A host processor controls and receives status from the Microsemi device using either a SPI or an I²C interface. The type of interface is selected using the startup state of the GPIO pins.

Figure 14 - Serial Interface Configuration

The selection between I2C and SPI interfaces is performed at start-up using GPIO[3] pin, right after pwr_b gets de-asserted. The GPIO pin need to be held at their appropriate value for 55 ms after the de-assertion of pwr_b, after which time they can be released and used as any other GPIO.

Both interfaces use seven bit address field and the device has eight bit address space. Hence, memory is divided in two pages. Page 0 with addresses 0x00 to 0x7E and Page 1 with addresses 0x80 to 0xFF. Writing 0x01 to Page Register at address 0x7F, toggles SPI/I2C accesses between Page 0 and Page 1.

| GPIO[3] | Serial Interface |
|---------|------------------|
| 0 | SPI |
| 1 | I2C |

Table 5 - Serial Interface Selection

6.1 Serial Peripheral Interface

The serial peripheral interface (SPI) allows read/write access to the registers that are used to configure, read status, and allow manual control of the device.

This interface supports two modes of access: Most Significant Bit (MSB) first transmission or Least Significant Bit (LSB) first transmission. The mode is automatically selected based on the state of **sck_scl** pin when the **cs_b_asel0** pin is active. If the **sck_scl** pin is low during **cs_b_asel0** activation, then MSB first timing is selected. If the **sck_scl** pin is high during **cs_b_asel0** activation, then LSB first timing is assumed.

The SPI port expects 7-bit addressing and 8-bit data transmission, and is reset when the chip select pin **cs_b_asel0** is high. During SPI access, the **cs_b_asel0** pin must be held low until the operation is complete. The first bit transmitted during the address phase of a transfer indicates whether a read (1) or a write (0) is being performed. Burst read/write mode is also supported by leaving the chip select signal **cs_b_asel0** low after a read or a write. The address will be automatically incremented after each data byte is read or written.

The serial peripheral interface supports half-duplex processor mode which means that during a write cycle to the device, output data from the **so_asel1** pin must be ignored. Similarly, the input data on the **si_sda** pin is ignored by the device during a read cycle.

Functional waveforms for the LSB and MSB first mode, and burst mode are shown in Figure 15, Figure 16 and Figure 17. Timing characteristics are shown in Table 7, Figure 27, and Figure 28.

6.1.1 Least Significant Bit (LSB) First Transmission Mode

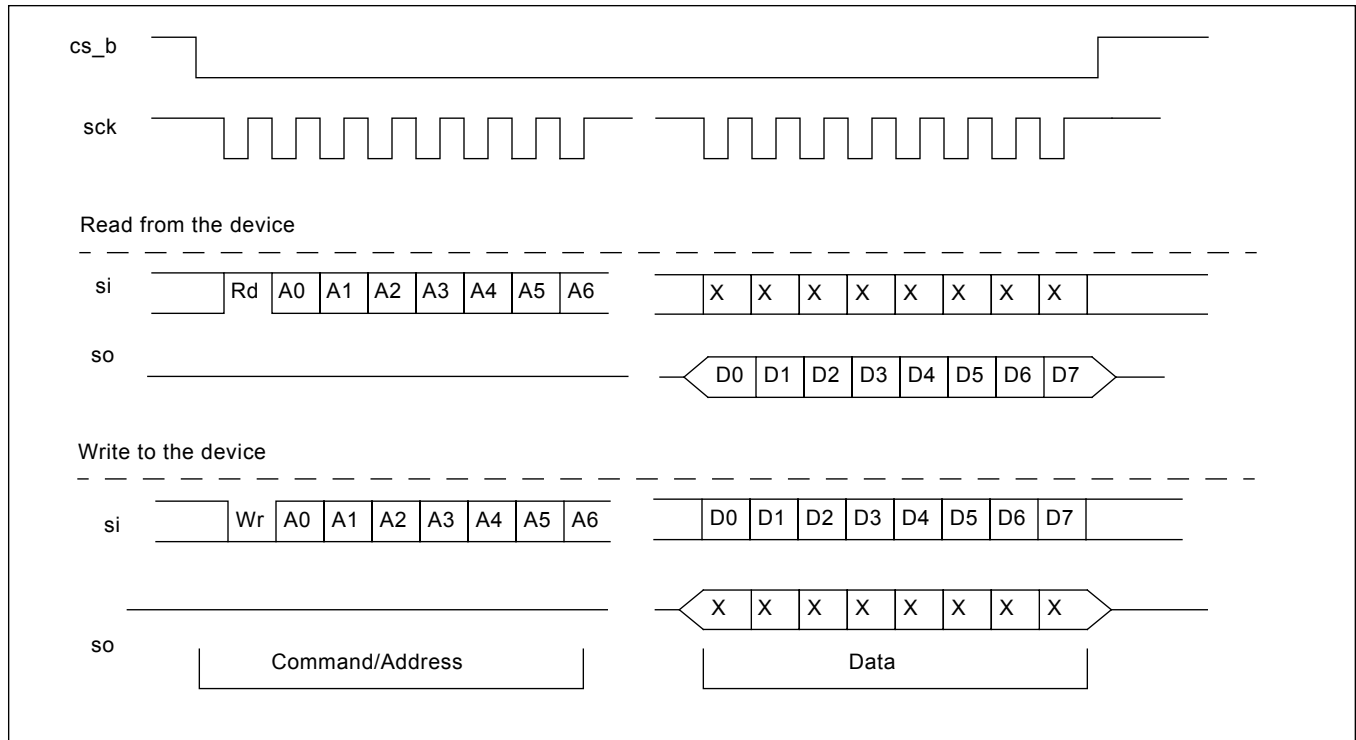

Figure 15 - Serial Peripheral Interface Functional Waveforms - LSB First Mode

6.1.2 Most Significant Bit (MSB) First Transmission Mode

Figure 16 - Serial Peripheral Interface Functional Waveforms - MSB First Mode

6.1.3 SPI Burst Mode Operation

Figure 17 - Example of a Burst Mode Operation

6.1.4 I²C Interface

The I²C controller supports version 2.1 (January 2000) of the Philips I²C bus specification. The port operates in slave mode with 7-bit addressing, and can operate in Standard (100 kbits/s) and Fast (400 kbits/s) mode. Burst mode is supported in both standard and fast modes.

Data is transferred MSB first and occurs in 1 byte blocks. As shown in Figure 18, a **write** command consists of a 7-bit device (slave) address, a 7-bit register address (0x00 - 0x7F), and 8-bits of data.

Figure 18 - I²C Data Write Protocol

A **read** is performed in two stages. A data write is used to set the register address, then a data read is performed to retrieve the data from the set address. This is shown in Figure 19.

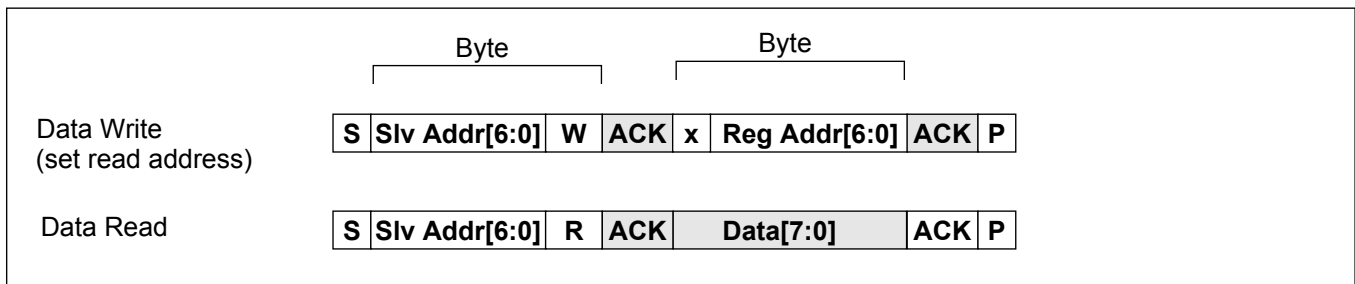

Figure 19 - I²C Data Read Protocol

The **7-bit device (slave) address** contains a 5-bit fixed address plus variable bits which are set with the **asel0**, and **asel1** pins. This allows multiple ZL30159s to share the same I²C bus. The address configuration is shown in Figure 20.

Figure 20 - I²C 7-bit Slave Address

The device also supports burst mode which allows multiple data write or read operations with a single specified address. This is shown in Figure 21 (write) and Figure 22 (read). The first data byte is written/read from the specified address, and subsequent data bytes are written/read using an automatically increment address. The maximum auto increment address of a burst operation is 0x7F. Any operations beyond this limit will be ignored. In other words, the auto increment address does not wrap around to 0x00 after reaching 0x7F.

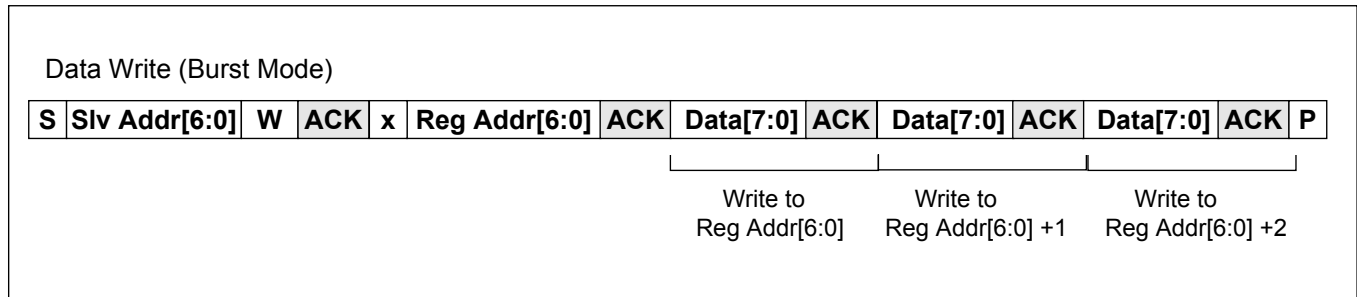

Figure 21 - I²C Data Write Burst Mode

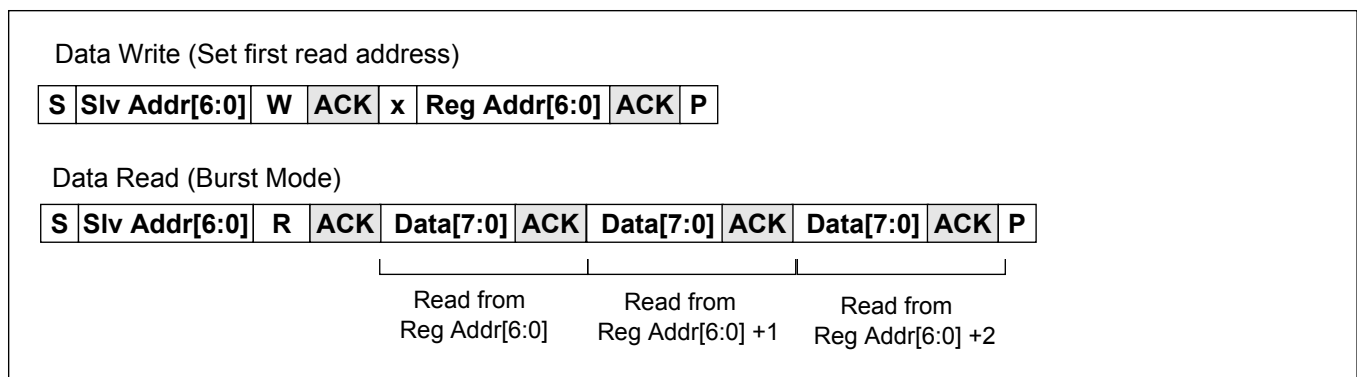

Figure 22 - I²C Data Read Burst Mode

7.0 Register Map

The device is mainly controlled by accessing software registers through the serial interface (SPI or I²C). The device can be configured to operate in a highly automated manner which minimizes its interaction with the system's processor, or it can operate in a manual mode where the system processor controls most of the operation of the device.

The simplest way to generate appropriate configuration for the device is to use the evaluation board GUI which can operate standalone (without the board). With GUI user can quickly set all required parameters and save the configuration to a text file.

Multi-byte Register Values

The device register map is based on 8-bit register access, so register values that require more than 8 bits must be spread out over multiple registers and accessed in 8-bit segments. When accessing multi-byte register values, it is important that the registers are accessed in the proper order—they must follow big endian addressing scheme. The 8-bit register containing the most significant byte (MSB) must be accessed first, and the register containing the least significant byte (LSB) must be accessed last. An example of a multi-byte register is shown in Figure 23. When writing a multi-byte value, the value is latched when the LSB is written.

Example:

The programmable input reference M and N 16 bit values defining the M/N ratio is programmed using a 32-bit value which is spread over four 8-bit registers. The MSB is contained in address 0x14 and the LSB in 0x17. When reading or writing this multi-byte value, the MSB must be accessed first, followed by the middle bytes, and the LSB last.

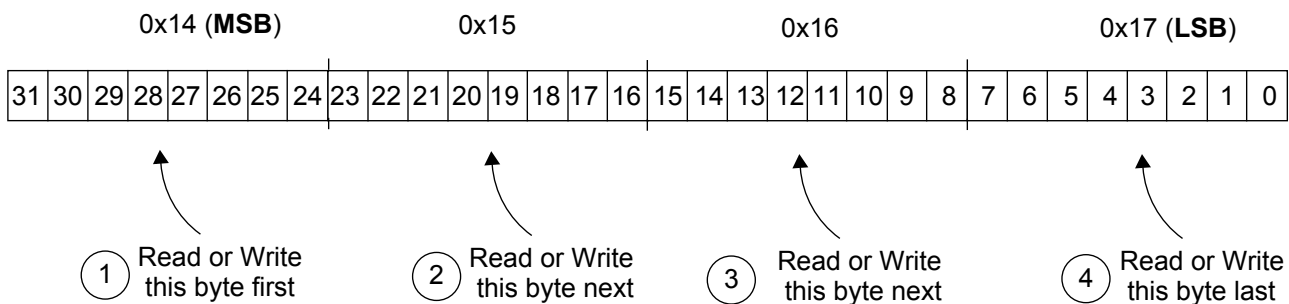

Figure 23 - Accessing Multi-byte Register Values

To assist in device setup, a configuration GUI is provided. The configuration GUI can directly configure the device evaluation board, but it also functions as a tool to provide details on how to configure different device registers.

Writing to registers

Writes to registers should follow following procedure:

- write 0x01 to Sticky R Lock Register at address 0x0D
- write to one or multiple register(s)
- write 0x00 to Sticky R Lock Register at address 0x0D

Time between two write accesses to the same register

User should wait at least 5 ms between two write accesses to the same register. This applies to all registers except Sticky R Lock Register at address 0x0D and page register at address 0x7F which can be accessed immediately.

Reading from Sticky Read (StickyR) Registers

Access to some status registers is defined as Sticky Read (StickyR). Procedure for accessing these registers is:

- clear status register(s) by writing 0x00 to it (please follow Writing to registers procedure shown above)
- wait for 5 ms
- read the status register(s)

The following table provides a summary of the registers available for status updates and configuration of the device. Devices with a custom OTP configuration will power-up with the custom configuration values instead of the default values.

| Reg_Addr (Hex) | Register Name | Default Value (Hex) | Description | Type |
|---|---------------------|---------------------------|--|---------|
| Miscellaneous Registers | | | | |
| 0x00 | id_reg | 0x09 | Chip ID and version identification. User should not write to this register. If this register is written to, the default value will be temporarily overwritten until the next reset. The temporary change of the default value will not affect the performance of the device. | R/W |
| Interrupts and Reference Monitor | | | | |
| 0x02 | ref_fail_isr_status | 0x00 | Reference failure status register | StickyR |
| 0x03 | dpll_isr_status | 0x00 | DPLL status register | StickyR |
| 0x04 | ref_fail_isr_mask | 0x00 | Reference failure interrupt service register mask | R/W |
| 0x05 | dpll_isr_mask | 0x00 | DPLL interrupt service register mask | R/W |
| 0x07 | ref_mon_fail | 0x00 | Ref failure indications | StickyR |
| 0x09 | ref_mon_fail_mask | 0x66 | Control register to mask failure indicator for Ref | R/W |
| 0x0A | ref_config | 0x00 | Configures input reference to be differential or single-ended | R/W |
| 0x0B | gst_disqualif_time | 0xAA | Control register for the guard soak timer disqualification time for the reference | R/W |
| 0x0C | gst_qualif_time | 0x55 | Control register for the guard soak timer qualification time for the reference | R/W |

Table 6 - Register Map

| Reg_Addr (Hex) | Register Name | Default Value (Hex) | Description | Type |
|--|-----------------------|---------------------------|--|---------|
| 0x0D | sticky_r_lock | 0x00 | Used to lock StickyR Status Registers from being updated by internal device logic | R/W |
| Input Frequency Configuration | | | | |
| 0x10:0x11 | ref_base_freq | 0x61A8 | Ref base frequency in Hz (16 bits, unsigned integer) | R/W |
| 0x12: 0x13 | ref_freq_multiple | 0x03E8 | Ref frequency as a multiple of the base frequency (16 bits, unsigned integer) | R/W |
| 0x14:0x17 | ref_ratio_M_N | 0x00010001 | Ref Mr and Nr values, used for multiplication ratio Mr/Nr (2 x 16 bits unsigned integers) | R/W |
| DPLL Configuration, State Machine Control and Monitor | | | | |
| 0x30 | dpll_ctrl | 0x0C | DPLL control register | R/W |
| 0x33 | dpll_mode_refsel | 0x03 | DPLL reference selection control or reference selection status | R/W |
| 0x34 | dpll_ref_fail_mask | 0x87 | Control register to mask each failure indicator (SCM, CFM and GST) used for automatic holdover | R/W |
| 0x44 | dpll_hold_lock_fail | 0x00 | DPLL lock and holdover status | StickyR |

| 0xF4 | pfm_mask_ho | 0xF0 | Control register to mask PFM failure indicator used for automatic holdover. | R/W |
| 0xF5 | pfm_mask_ref_fail | 0x00 | Control register to mask PFM failure indication for the input reference. | R/W |
| 0xF7 | pfm_range_ref | 0x33 | Precise Frequency Monitoring for the input reference | R/W |

Table 6 - Register Map (continued)

8.0 Detailed Register Map

| Register_Address: 0x00 Register Name: id_reg Default Value: 0x09 Type: R/W | | |
|--|------------------|--|
| Bit Field | Function Name | Description |
| 4:0 | chip_id | Chip Identification = 0b01001 |
| 6:5 | chip_revision | Chip revision number 0b11: RevE 0b00: Chip revision specified in register 0xC6 |
| 7 | ready_indication | After reset this bit will be undefined for up to 45 ms. After 45 ms this bit will go low indicating that the device is finalizing self-initialization. Finally, this bit will go high indicating that the device is ready to be programmed by the user. It can take up to 55 ms for this bit to go high after the reset. |

| Register_Address: 0x02 Register Name: ref_fail_isr_status Default Value: 0x00 Type: StickyR | | |
|---|---------------|--|
| Bit Field | Function Name | Description |
| 0 | ref_fail | This bit is set to 1 when ref has a failure. The device will set this bit to high when ref_fail_mask bit of the ref_fail_isr_mask register at address 0x04 is high and conditions for ref failure are satisfied. When this bit is set to high, it also sets IRQ line to high. |
| 7:1 | reserved | Leave as default |

Register_Address: **0x03**
 Register Name: **dpll_isr_status**
 Default Value: **0x00**
 Type: StickyR

| Bit Field | Function Name | Description |
|-----------|-------------------|--|
| 0 | dpll_holdover | The device will set this bit to high when dpll_holdover_mask bit of the dpll_interrupt_mask register at address 0x05 is high and DPLL went into holdover mode. When this bit is set to high, it also sets IRQ line to high. |
| 1 | dpll_loss_of_lock | The device will set this bit to high when 'dpll_loss_of_lock_mask bit of the dpll_interrupt_mask register at address 0x05 is high and DPLL has lost lock. When this bit is set to high, it also sets IRQ line to high. |
| 7:2 | reserved | Leave as default |

Register_Address: **0x04**
 Register Name: **ref_fail_isr_mask**
 Default Value: **0x00**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|-------------------|--|
| 0 | ref_fail_isr_mask | Reference failure interrupt generation mask. When set to zero disables interrupt generation and appearance in the Reference Status ISR register. |
| 7:1 | reserved | Leave as default |

Register_Address: **0x05**
 Register Name: **dpll_isr_mask**
 Default Value: **0x00**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|--------------------|---|
| 0 | dpll_holdover_mask | DPLL holdover indication mask. When set to zero disables interrupt generation and appearance in the DPLL Status ISR register. |

Register_Address: **0x05**
 Register Name: **dpll_isr_mask**
 Default Value: **0x00**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|------------------------|---|
| 1 | dpll_loss_of_lock_mask | DPLL loss of lock indication mask. When set to zero disables interrupt generation and appearance in the DPLL Status ISR register. |
| 7:2 | reserved | Leave as default. |

Register_Address: **0x07**
 Register Name: **ref_mon_fail**
 Default Value: **0x00**
 Type: StickyR

| Bit Field | Function Name | Description |
|-----------|---------------|--|
| 0 | ref_fail_los | Reference Loss Of Signal (LOS) indicator. The device will set this bit to high when external Ref 0 LOS signal (typically from PHY device), applied to selected GPIO, goes high. The Ref LOS signal indicator can be associated with any of available GPIOs pins through the 'GPIO function' registers. Note: this bit is not maskable. |
| 1 | ref_fail_scm | Reference Single Cycle Monitor (SCM) indicator. This bit is set high whenever Single Cycle Failure on Reference occurs. Note: this bit is not maskable. |
| 2 | ref_fail_cfm | Reference coarse frequency monitoring (CFM) indicator. This bit is set high whenever coarse frequency monitoring failure on Reference occurs. Note: this bit is not maskable. |
| 3 | ref_fail_gst | Guard Soak Timer (GST) failure indicator on Reference. This bit is set high whenever Reference guard soak timer expires. Note: this bit is not maskable. |
| 7:4 | reserved | Leave as default |

Register_Address: **0x09**
 Register Name: **ref_mon_fail_mask**
 Default Value: **0x66**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|---------------|--|
| 3:0 | ref_fail_mask | <p>Masks failure indicators (LOS,SCM, CFM, and GST) for input reference.</p> <p>bit 0: LOS (Loss of Clock) bit 1: SCM (Single Cycle Monitor) bit 2: CFM (Coarse Frequency Monitor) bit 3: GST (Guard Soak Timer)</p> <p>0: failure bit is masked (disabled) 1: failure bit is un-masked (enabled)</p> <p>Note: When set low these bits will mask corresponding Reference failure indicators in Reference Failure Interrupt Status Register at address 0x02. They will not affect bits in Reference Monitoring Failure Mask Register at address 0x07 because bits in Reference Monitoring Failure Mask Register are not maskable.</p> |
| 7:4 | reserved | Leave as default |

Register_Address: **0x0A**
 Register Name: **ref_config**
 Default Value: **0x00**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|------------------------|---|
| 0 | ref_pre-divider_enable | <p>When set high, the Reference input clock will be divided by 2 prior to being fed to DPLL. All registers, which depend on the frequency of the input reference will have to be programmed with half of the reference frequency.</p> <p>When set low, the Reference is fed directly to DPLL.</p> |
| 3:1 | reserved | Leave as default |
| 4 | ref_diff_input_enable | <p>When set high, the device expects differential clock at Ref input pins (Ref_p and Ref_n).</p> <p>When set low, the device expects single-ended clock at Ref_p input pin, and Ref_n input should be connected to ground.</p> |
| 7:5 | reserved | Leave as default |

Register_Address: **0x0B**
 Register Name: **gst_disqualif_time**
 Default Value: **0xAA**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|-------------------------|---|
| 1:0 | ref_gst_disqualif_timer | Selects time to disqualify input reference after detection of either the Ref CFM or Ref SCM indicators. 00: minimum delay 01: 10 ms 10: 50 ms (default) 11: 2.5 s |
| 7:2 | reserved | Leave as default |

Register_Address: **0x0C**
 Register Name: **gst_qualif_time**
 Default Value: **0x55**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|----------------------|---|
| 1:0 | ref_gst_qualif_timer | Selects time to qualify input reference after deassertion of both the Ref CFM and Ref SCM indicators. 00: 2 x selected Ref GST disqualify time 01: 4 x selected Ref GST disqualify time (default) 10: 6 x selected Ref GST disqualify time 11: 8 x selected Ref GST disqualify time |
| 7:2 | reserved | Leave as default |

Register_Address: **0x0D**
 Register Name: **sticky_r_lock**
 Default Value: **0x00**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|---------------|--|
| 7:0 | sticky_r_lock | <p>This register is used when accessing StickyR status registers. Writing 0x01 to this register locks the status register from being updated by internal logic.</p> <p>Writing 0x00 to this register enables internal updates of StickyR status registers</p> <p>Please refer to Reading from Sticky Read (StickyR) registers and Writing to registers procedure at the beginning of 7.0, “Register Map” section.</p> |

Register_Address: **0x10:0x11**
 Register Name: **ref_base_freq**
 Default Value: **0x61A8**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|---------------|---|
| 15:0 | ref_base_freq | <p>Unsigned binary value of these bits represents Ref base frequency Br in Hz. Values for Br that can be programmed:</p> <p>0x03E8 for 1 kHz, 0x07D0 for 2 kHz, 0x1388 for 5 kHz, 0x186A for 6.25 kHz, 0x1F40 for 8 kHz, 0x2710 for 10 kHz, 0x30D4 for 12.5 kHz, 0x61A8 for 25 kHz, 0x9C40 for 40 kHz.</p> <p>Note 1: Other Br rates can be supported, please contact Microsemi application support team if another specific Br rate is required</p> <p>Note 2: in order to write 16 bit value to this register (and any other register that is bigger than 8 bits), the most significant byte has to be written to the lower address and least significant byte has to be written to the higher address. Hence, memory mapping follows big endian.</p> |

Register_Address: **0x12:0x13**
 Register Name: **ref_freq_multiple**
 Default Value: **0x03E8**
 Type: R/W

| Bit Field | Function Name | Description | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------------------|-------------------|---|---------------------|-------------------|----------------------------|-----------|----------------|--------------|-----------|----------------|--------------|-----------|-----------------|--------------|-----------|-----------------|---------------|---------|-----------------|----------------|------------|-----------------|---------------|------------|-----------------|---------------|-------|----------------|------------|
| 15:0 | ref_freq_multiple | <p>Unsigned binary value of these bits represents Ref base frequency multiplication factor Kr. For regular (non-FEC) reference frequencies, the 'Base frequency' number Br multiplied by the 'Base frequency multiple' number Kr has to equal the reference frequency in Hz.</p> <p>Examples of some references frequencies and appropriate values that can be programmed for Br and Kr to match that reference frequency:</p> <table> <tr> <th>Reference frequency</th><th>Base frequency Br</th><th>Base frequency multiple Kr</th></tr> <tr> <td>2.048 MHz</td><td>8 kHz (0x1F40)</td><td>256 (0x0100)</td></tr> <tr> <td>1.544 MHz</td><td>8 kHz (0x1F40)</td><td>193 (0x00C1)</td></tr> <tr> <td>19.44 MHz</td><td>40 kHz (0x9C40)</td><td>486 (0x01E6)</td></tr> <tr> <td>177.5.MHz</td><td>25 kHz (0x61A8)</td><td>7100 (0x1BBC)</td></tr> <tr> <td>125 MHz</td><td>40 kHz (0x9C40)</td><td>18752 (0x4940)</td></tr> <tr> <td>156.25.MHz</td><td>25 kHz (0x61A8)</td><td>6250 (0x186A)</td></tr> <tr> <td>155.52 MHz</td><td>40 kHz (0x9C40)</td><td>3888 (0x0F30)</td></tr> <tr> <td>8 kHz</td><td>1 kHz (0x03E8)</td><td>8 (0x0008)</td></tr> </table> | Reference frequency | Base frequency Br | Base frequency multiple Kr | 2.048 MHz | 8 kHz (0x1F40) | 256 (0x0100) | 1.544 MHz | 8 kHz (0x1F40) | 193 (0x00C1) | 19.44 MHz | 40 kHz (0x9C40) | 486 (0x01E6) | 177.5.MHz | 25 kHz (0x61A8) | 7100 (0x1BBC) | 125 MHz | 40 kHz (0x9C40) | 18752 (0x4940) | 156.25.MHz | 25 kHz (0x61A8) | 6250 (0x186A) | 155.52 MHz | 40 kHz (0x9C40) | 3888 (0x0F30) | 8 kHz | 1 kHz (0x03E8) | 8 (0x0008) |

Register_Address: **0x14:0x17**
 Register Name: **ref_ratio_M_N**
 Default Value: **0x00010001**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|------------------|---|
| 15:0 | ref_FEC_denom_Nr | <p>Unsigned binary value of Mr bits, in combination with unsigned binary value of Nr bits represents Ref FEC multiplication ratio. For FEC reference frequencies, the 'Base frequency' number Br multiplied by the 'Base frequency multiple' number Kr, multiplied by Mr and divided by Nr has to equal the reference frequency in Hz;</p> $\text{Ref_freq [Hz]} = \text{Br} \times \text{Kr} \times \text{Mr} / \text{Nr}$ <p>For regular (non-FEC) reference frequencies, Mr and Nr should be programmed to 0x0001 (default values)</p> <p>Examples of some FEC references frequencies and appropriate values that can be programmed for the Br, Kr, Mr and Nr register to match that FEC reference frequency:</p> |
| 31:16 | ref_FEC_numer_Mr | <p>a) OC-192 mode, standard EFEC for long reach:</p> <p>Reference frequency: 155.52 MHz x 255 / 237 Base frequency Br: 40 kHz (0x9C40) Base frequency multiple Kr : 3888 (0x0F30) FEC ratio Numerator Mr: 255 (0x00FF) FEC ratio denominator Nr: 237 (0x00ED)</p> <p>b) Long reach 10GE mode, double rate conversion:</p> <p>Reference frequency: 156.25 MHz x 66/64 x 255/238 Base frequency Br: 25 kHz (0x61A8) Base frequency multiple Kr : 6250 (0x186A) FEC ratio Numerator Mr: 66x255 (0x41BE) FEC ratio denominator Nr: 64x238 (0x3B80))</p> |

Register_Address: **0x30**
 Register Name: **dpil_ctrl**
 Default Value: **0x0C**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|---------------|------------------|
| 1:0 | Reserved | Leave as Default |

Register_Address: **0x30**
 Register Name: **dppll_ctrl**
 Default Value: **0x0C**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|-------------------------|--|
| 3:2 | dppll_phase_slope_limit | Selects phase slope limit for DPLL 00: 61 usec/sec 01: 7.5 usec/sec 10: 0.885 usec/sec 11: unlimited |
| 4 | dppll_tie_clear_enable | Set high to align phase of the DPLL output clock with the phase of input reference. |
| 7:5 | dppll_loop_bandwidth | Selects loop bandwidth of DPLL: 000: 14 Hz 001: 28 Hz 010: 56 Hz 011: 112 Hz 100: 224 Hz 101: 448 Hz 110: 896 Hz 111: 30 mHz |

Register_Address: **0x33**
 Register Name: **dppll_mode_refsel**
 Default Value: **0x03**
 Type: R/W

| Bit Field | Function Name | Description |
|-----------|---------------|---|
| 1:0 | dppll_mode | Selects DPLL mode of operation. 00: freerun mode 01: forced holdover mode 10: reserved 11: automatic mode In 'automatic mode', locking is based on the input reference availability. In this mode, DPLL will go to holdover only if the input reference is not available. When the 'forced holdover mode' is programmed, the input reference is ignored and DPLL has to go to holdover. When the 'freerun mode' is selected, the DPLL has to generate all its output clocks based only on the oscillator OSC1 input. |
| 7:2 | reserved | Leave as default |

Register_Address: **0x34**

Register_Address: **0x73:0x76**
 Register Name: **central_freq_offset**
 Default Value: **0x046AAAAB**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------|--|
| 31:0 | central_freq_offset | <p>2's complement binary value of these bits represent central frequency offset for the device. This value should be used to compensate for oscillator inaccuracy, or make the device look like Numerically Controlled Oscillator (NCO). This register controls central frequency of all 4 Synthesizers. Expressed in steps of $\pm 2^{-32}$ of nominal setting.</p> <p>When oscillator inaccuracy is known: $\text{inacc_osc} = (\text{f_osc} - \text{f_nom})/\text{f_nom}$ (usually specified in ppm), value to be programmed in this register is calculated as per the following formula:</p> <p>$X = (1/(1 + \text{inacc_osc}) - 1) * 2^{32}$, when $\text{f_osc} < \text{f_nom}$ $X = (1/(1 + \text{inacc_osc})) * 2^{32}$, when $\text{f_osc} > \text{f_nom}$, where inacc_osc - represents oscillator frequency inaccuracy, f_osc - represents oscillator frequency, and f_nom - represents oscillator nominal frequency (i.e., 25 MHz, 20 MHz)</p> <p>Generally, when the oscillator frequency is lower than the nominal, frequency offset has to be programmed to compensate it in opposite direction, i.e. frequency offset has to be positive, and vice versa.</p> <p>Example 1): if oscillator inaccuracy is -2% ($\text{f_osc} = 24.5 \text{ MHz}$; $\text{inacc_osc} = (\text{f_osc} - 25 \text{ MHz})/25\text{MHz} = -0.02$), $X = (1/(1 + (-0.02)) - 1) * 2^{32} = (1/0.98 - 1) * 2^{32} = 87652394 = 0x0539782A$</p> <p>Example 2): if oscillator inaccuracy is +2% ($\text{f_osc} = 25.5 \text{ MHz}$; $\text{inacc_osc} = (\text{f_osc} - 25 \text{ MHz})/25\text{MHz} = 0.02$), $X = (1/(1 + 0.02)) * 2^{32} = (1/1.02) * 2^{32} = 4210752251 = 0xFAFAFAFB$</p> <p>When NCO behavior is desired, the output frequency should be calculated as per formula: $\text{fout} = (1 + X/2^{32}) * \text{finit}$ where X -represent 2's complement number specified in this register finit - initial frequency set by Bs, Ks, Ms, Ns and postdivider number for particular VCO fout - output frequency</p> <p>Note 1: The default value is based on 24.576 MHz oscillator. The default value should be changed to 0x00000000 for 20 MHz oscillator. Note 2: Central Frequency Offset should not exceed $\pm 5\%$ off nominal.</p> |

| 6:0 | gpio_pin2_table_address | Unsigned binary value of these bits represents bit address in the control or status table, depending on 'GPIO2 control or status select' bit. The control and status table consist of 128 bits each. Default: hpdiffo enable. |
| 7 | gpio_pin2_con_or_stat_sel | Selects whether GPIO2 is input (control) pin or output (status) pin. Selection: 0 = control 1 = status |

Register_Address: 0xE3**Register Name: gpio_function_pin3****Default Value: 0x00****Type: R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------------|---|
| 6:0 | gpio_pin3_table_address | Unsigned binary value of these bits represents bit address in the control or status table, depending on 'GPIO3 control or status select' bit. The control and status table consist of 128 bits each. Default: GPIO pin unused. |
| 7 | gpio_pin3_con_or_stat_sel | Selects whether GPIO3 is input (control) pin or output (status) pin. Selection: 0 = control 1 = status |

Register_Address: 0xE4**Register Name: gpio_function_pin4****Default Value: 0x00****Type: R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------------|---|
| 6:0 | gpio_pin4_table_address | Unsigned binary value of these bits represents bit address in the control or status table, depending on 'GPIO4 control or status select' bit. The control and status table consist of 128 bits each. Default: GPIO pin unused. |
| 7 | gpio_pin4_con_or_stat_sel | Selects whether GPIO4 is input (control) pin or output (status) pin. Selection: 0 = control 1 = status |

Register_Address: **0xE5**
 Register Name: **gpio_function_pin5**
 Default Value: **0x00**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------------|--|
| 6:0 | gpio_pin5_table_address | Unsigned binary value of these bits represents bit address in the control or status table, depending on 'GPIO5 control or status select' bit. The control and status table consist of 128 bits each. Default: GPIO pin unused.. |
| 7 | gpio_pin5_con_or_stat_sel | Selects whether GPIO5 is input (control) pin or output (status) pin. Selection: 0 = control 1 = status |

Register_Address: **0xE6**
 Register Name: **gpio_function_pin6**
 Default Value: **0x72**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------------|--|
| 6:0 | gpio_pin6_table_address | Unsigned binary value of these bits represents bit address in the control or status table, depending on 'GPIO6 control or status select' bit. The control and status table consist of 128 bits each. Default: Enable hpoutclk1. |
| 7 | gpio_pin6_con_or_stat_sel | Selects whether GPIO6 is input (control) pin or output (status) pin. Selection: 0 = control 1 = status |

Register_Address: **0xEC**
 Register Name: **dpll_ctrl2**
 Default Value: **0x00**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|------------------------|--|
| 4:0 | Holdover Storage delay | The storage delay is set using the formula $\text{Value} = \text{round}(8 * \log(\text{StorageDelay}/10))$ Note: StorageDelay is in ms. Example values: 0x00: 10 ms 0x08: 100 ms 0x10: 1 s 0x1D: 42.2 s |
| 5 | Reserved | Leave as default |
| 7:6 | Input edge sensitivity | Select the inout sign of the signal Note: The pulse options select the middle between the edges Selection: 00: positive (rising) edge 01: negative (falling) edge 10: low pulse 11: high pulse |

Register_Address: **0xED**
 Register Name: **dpll_holdpull**
 Default Value: **0x07**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|-----------------------|---|
| 2:0 | Hold-in/pull-in range | Selects the hold-in/pull-in range for the DPLL Selection: 000: 12 ppm 001: 52 ppm 010: 83 ppm 011: 130 ppm 100: 400 ppm 101: reserved 110: reserved 111: unlimited |
| 7:3 | Reserved | |

Register_Address: **0xF4**
Register Name: **pfm_mask_ho**
Default Value: **0xF0**
Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|---------------------------------|---|
| 3:0 | Reserved | Leave as default |
| 4 | DPLL holdover mask on PFM alarm | Set to 0 to mask DPLL holdover on PFM alarm |
| 7:5 | Reserved | Leave as default |

Register_Address: **0xF5**
Register Name: **pfm_mask_reffail**
Default Value: **0x00**
Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|-------------------|---|
| 0 | Ref Fail PFM Mask | Set to 0 to mask PFM alarm indication for the input reference |
| 7:1 | Reserved | Leave as default |

Register_Address: **0xF7**
 Register Name: **pfm_range**
 Default Value: **0x33**
 Type: **R/W**

| Bit Field | Function Name | Description |
|-----------|---------------|--|
| 2:0 | pfm_range | <p>This values controls the acceptance and rejection ranges for the frequency monitor for the input reference. Frequencies within the lower range will always be accepted and frequencies outside of the high range will always be rejected. The state remains unchanged for frequencies between the two ranges.</p> <p>Selection Acceptance Range (ppm), Rejection Range (ppm)</p> <p>000: 9.2, 12 001: 40, 52 010: 64, 83 011: 100, 130 100: 13.8, 18 101: 24.6, 32 110: 33.6, 47.5 111: 52, 67.5</p> |
| 7:3 | Reserved | Leave as default |

9.0 AC and DC Electrical Characteristics

Absolute Maximum Ratings*

| | Parameter | Symbol | Min. | Max. | Units |
|---|------------------------------|---------------|------|----------------|-------|
| 1 | Supply voltage | V_{DD_R} | -0.5 | 4.6 | V |
| 2 | Core supply voltage | V_{CORE_R} | -0.5 | 2.5 | V |
| 3 | Voltage on any digital pin | V_{PIN} | -0.5 | 6 | V |
| 4 | Voltage on osci and osco pin | V_{OSC} | -0.3 | $V_{DD} + 0.3$ | V |
| 5 | Storage temperature | T_{ST} | -55 | 125 | °C |

* Exceeding these values may cause permanent damage. Functional operation under these conditions is not implied.

* Voltages are with respect to ground (GND) unless otherwise stated

Recommended Operating Conditions*

| | Characteristics | Sym | Min. | Typ. | Max. | Units |
|---|-----------------------|---------------------------|-------|------|-------|-------|
| 1 | Supply voltage | V_{DD_IO} AV_{DD} | 3.135 | 3.30 | 3.465 | V |
| 2 | Core supply voltage | V_{CORE} AV_{CORE} | 1.71 | 1.80 | 1.89 | V |
| 3 | Operating temperature | T_A | -40 | 25 | 85 | °C |

* Voltages are with respect to ground (GND) unless otherwise stated

DC Electrical Characteristics* - Power - Core

| | Characteristics | Sym | Typ. | Max. | Units | Notes |
|---|---------------------------------|-----------------------|------|------|-------|-------|
| 1 | Core supply current (Vcore) | I_{CORE} (Vdd 3.3V) | 46 | 48 | mA | |
| | | I_{CORE} (Vdd 1.8V) | 102 | 109 | mA | |
| 2 | Current for HP Synthesis Engine | I_{SYN} (Vdd 3.3V) | 57 | 73 | mA | |
| | | I_{SYN} (Vdd 1.8V) | 0.2 | 1 | mA | |

DC Electrical Characteristics* - Inputs

| | Characteristics | Sym. | Min. | Typ. | Max. | Units | Notes |
|---|--|-----------|------------------------|------|------------------------|-------|-----------------------|
| 1 | CMOS high-level input voltage | V_{CIH} | $0.7 \cdot V_{DD_IO}$ | | | V | |
| 2 | CMOS low-level input voltage | V_{CIL} | | | $0.3 \cdot V_{DD_IO}$ | V | |
| 3 | CMOS Input leakage current | I_{IL} | -10 | | 10 | μA | $V_I = V_{DD}$ or 0 V |
| 4 | Differential input common mode voltage | V_{CM} | 1.1 | | 2.0 | V | |
| 5 | Differential input voltage difference | V_{ID} | 0.25 | | 1.0 | V | |

AC/DC Electrical Characteristics* - OSCi Input

| | Characteristics | Sym. | Min. | Typ. | Max. | Units | Notes |
|---|-------------------------------|-----------|------|------|------|---------|-----------------------|
| 1 | CMOS high-level input voltage | V_{CIH} | 2.0 | | | V | |
| 2 | CMOS low-level input voltage | V_{CIL} | | | 0.8 | V | |
| 3 | Input leakage current | I_{IL} | -10 | | 10 | μA | $V_I = V_{DD}$ or 0 V |
| 4 | Duty Cycle | | 40 | | 60 | % | |

DC Electrical Characteristics* - High Performance Outputs

| | Characteristics | Sym. | Min. | Typ. | Max. | Units | Notes |
|---|----------------------------------|----------|---------------------|------|---------------------|-------|-------------------------------|
| 1 | HPCMOS High-level output voltage | V_{OH} | $0.8 \cdot AV_{DD}$ | | | V | $I_{OH} = 2mA$ $C_L = 5pF$ |
| 2 | HPCMOS Low-level output voltage | V_{OL} | | | $0.2 \cdot AV_{DD}$ | V | $I_{OL} = 2mA$ $C_L = 5pF$ |

AC Electrical Characteristics[†] - Output Timing Parameters Measurement Voltage Levels (see Figure 24)

| | Characteristics | Sym. | CMOS | Units |
|---|--------------------------------------|---------------------|-------------|-------|
| 1 | Threshold Voltage | $V_{T\text{-CMOS}}$ | $0.5V_{DD}$ | V |
| 2 | Rise and Fall Threshold Voltage High | V_{HM} | $0.8V_{DD}$ | V |
| 3 | Rise and Fall Threshold Voltage Low | V_{LM} | $0.2V_{DD}$ | V |

* Supply voltage and operating temperature are as per Recommended Operating Conditions.

* Voltages are with respect to ground (GND) unless otherwise stated

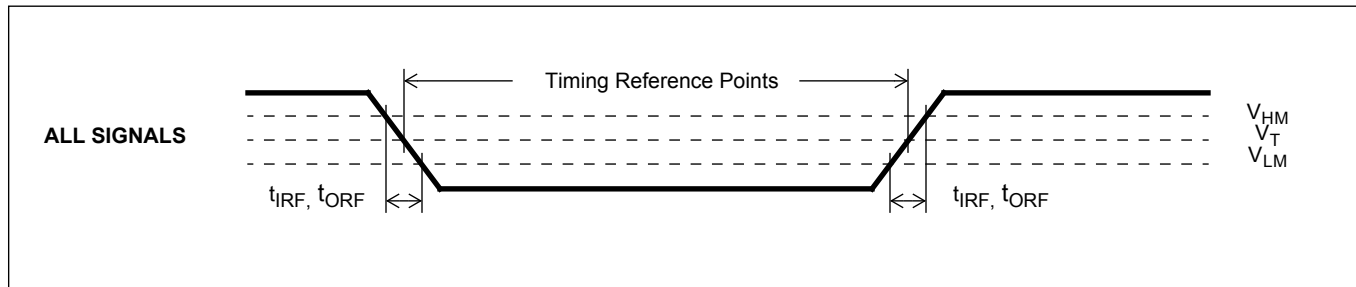

Figure 24 - Timing Parameter Measurement Voltage Levels

AC Electrical Characteristics* - Inputs (see Figure 25).

| | Characteristics | Symbol | Min. | Typ. | Max. | Units |
|---|---|--------------|------|------|-------|-------|
| 1 | Input reference Frequency (CMOS Inputs) | $1/t_{REFP}$ | | | 177.5 | MHz |
| 2 | Input reference Frequency (LVPECL Inputs) | $1/t_{REFP}$ | | | 750 | MHz |
| 3 | Input reference pulse width high or low | t_{REFW} | 0.55 | | | ns |

* Supply voltage and operating temperature are as per Recommended Operating Conditions

AC Electrical Characteristics* - Input To Output Timing (see Figure 25)

| | Characteristics | Symbol | Min. | Typ. | Max. | Units |
|---|---|----------------|------|------|------|-------|
| 1 | Input reference to hpoutclk0 output clock (with same frequency) delay | t_{HP_REFD} | | 0 | | ns |

* Supply voltage and operating temperature are as per Recommended Operating Conditions.

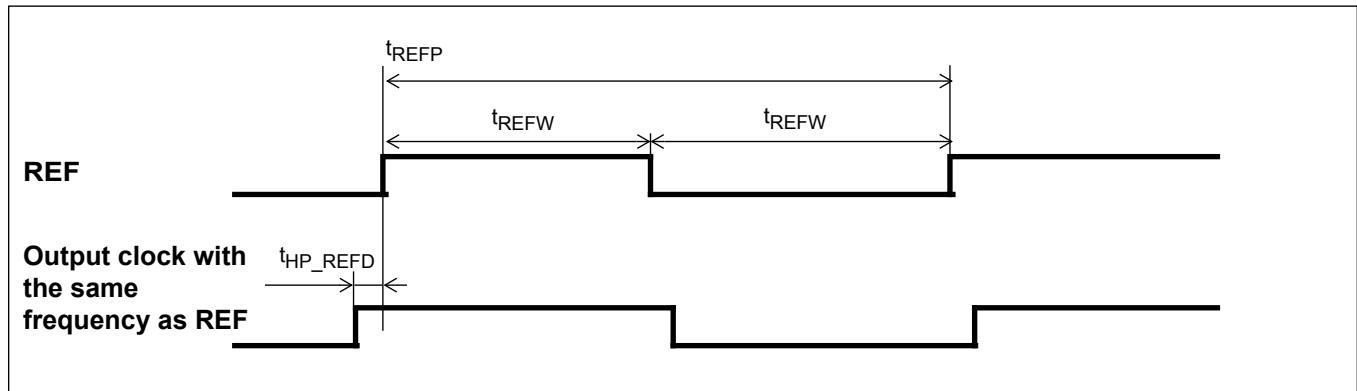

Figure 25 - Input To Output Timing for hpoutclk0

AC Electrical Characteristics* - Outputs (see Figure 26).

| | Characteristics | Sym. | Min. | Typ. | Max. | Units | Notes |
|---|---|--------------------|------|------|-------|------------|-----------|
| 1 | Clock skew between outputs | $t_{OUT2OUTD}$ | | 0 | | ns | |
| 2 | Output clock Duty Cycle | t_{PWH}, t_{PWL} | 45% | 50% | 55% | Duty Cycle | |
| 3 | LVC MOS output clock rise and fall time | t_r / t_f | 620 | 950 | 1490 | ps | 10pF load |
| 4 | Output Clock Frequency (hpoutclk) | F_{hpout} | | | 177.5 | MHz | |

* Supply voltage and operating temperature are as per Recommended Operating Conditions

Figure 26 - Output Timing Referenced To hpclkout0

Functional waveforms and timing characteristics for the LSB first mode are shown in Figure 27, and Figure 28 describe the MSB first mode. Table 7 shows the timing specifications.

| Specification | Name | Min. | Max. | Units |
|---|-------|------|------|-------|
| sck period | tcyc | 124 | | ns |
| sck pulse width low | tclkl | 62 | | ns |
| sck pulse width high | tclkh | 62 | | ns |
| si setup (write) from sck rising | trxs | 10 | | ns |
| si hold (write) from sck rising | trxh | 10 | | ns |
| so delay (read) from sck falling | txd | | 25 | ns |
| cs_b setup from sck falling (LSB first) | tcssi | 20 | | ns |
| cs_b setup from sck rising (MSB first) | tcssm | 20 | | ns |
| cs_b hold from sck falling (MSB first) | tcshm | 10 | | ns |
| cs_b hold from sck rising (LSB first) | tcshi | 10 | | ns |
| cs_b to output high impedance | tohz | | 60 | ns |

Table 7 - Serial Peripheral Interface Timing

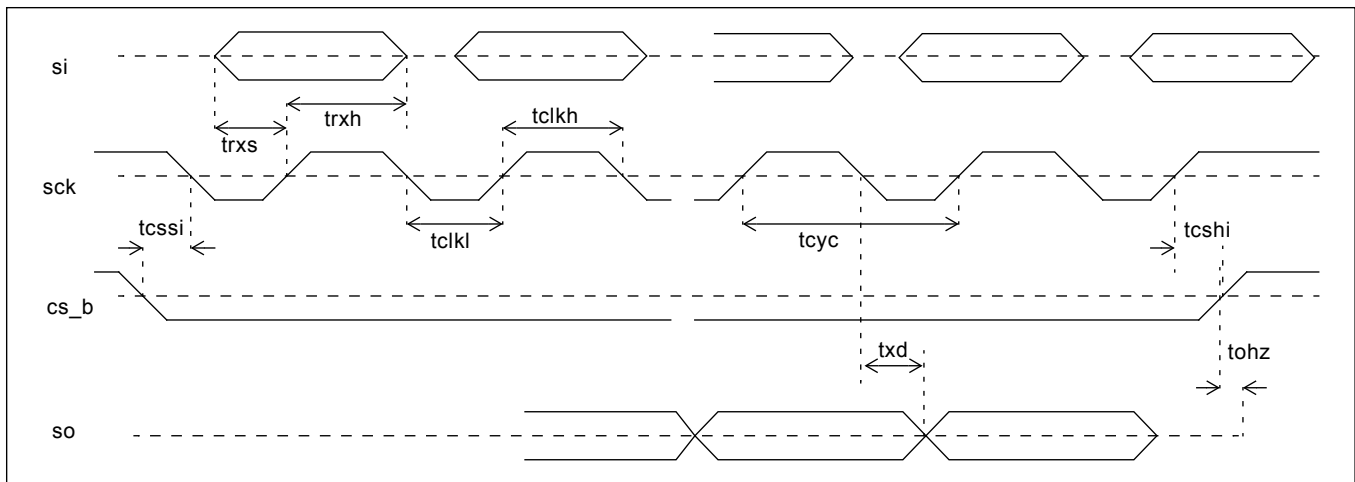

Figure 27 - Serial Peripheral Interface Timing - LSB First Mode

Figure 28 - Serial Peripheral Interface Timing - MSB First Mode

The timing specification for the I²C interface is shown in Figure 29 and Table 8.

| Specification | Name | Min. | Typ. | Max. | Units | Note |
|--|--------------|---------------|------|------|-------|--|
| SCL clock frequency | f_{SCL} | 0 | | 400 | kHz | |
| Hold time START condition | $t_{HD:STA}$ | 0.6 | | | us | |
| Low period SCL | t_{LOW} | 1.3 | | | us | |
| Hi period SCL | t_{HIGH} | 0.6 | | | us | |
| Setup time START condition | $t_{SU:STA}$ | 0.6 | | | us | |
| Data hold time | $t_{HD:DAT}$ | 0 | | 0.9 | us | |
| Data setup time | $t_{SU:DAT}$ | 100 | | | ns | |
| Rise time | t_r | | | | ns | Determined by choice of pull-up resistor |
| Fall time | t_f | $20 + 0.1C_b$ | | 250 | ns | |
| Setup time STOP condition | $t_{SU:STO}$ | 0.6 | | | us | |
| Bus free time between STOP/START | t_{BUF} | 1.3 | | | us | |
| Pulse width of spikes which must be suppressed by the input filter | t_{SP} | 0 | | 50 | ns | |
| Max capacitance for each I/O pin | | | | 10 | pF | |

Table 8 - I²C Serial Microport Timing

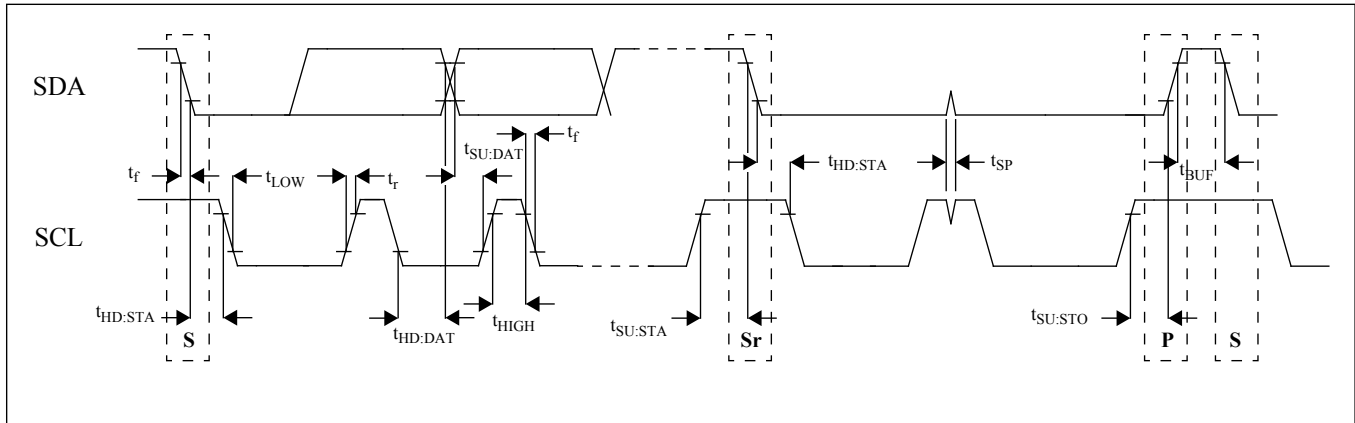

Figure 29 - I²C Serial Microport Timing

10.0 Performance Characterization

10.1 Output Clocks Jitter Generation

| Output Frequency | Jitter Measurement Filter | Max. | Units | Notes |
|------------------|---------------------------|------|-------------------|-------|
| 25 MHz | 12 kHz - 5 MHz | 0.81 | ps _{rms} | |
| 77.76 MHz | 12 kHz - 20 MHz | 1.25 | ps _{rms} | |
| 125 MHz | 12 kHz - 20 MHz | 1.01 | ps _{rms} | |
| 156.25 MHz | 12 kHz - 20 MHz | 1.03 | ps _{rms} | |

Table 9 - Jitter Generation Specifications - HPOUT Outputs

10.2 DPLL Performance Characteristics

| | Characteristics | Min. | Typ. | Max. | Units | Notes |
|---|----------------------------|-------|------|---------|-------|---|
| 1 | Pull-in/Hold-in Range | +/-52 | | +/-3900 | ppm | user selectable |
| 2 | Frequency Lock Time | | | 1 | sec | loop bandwidth larger or equal than 14 Hz and unlimited phase slope |
| | | | | 90 | sec | loop bandwidth 30mHz |
| 3 | Entry into Holdover MTIE | | | 5 | nsec | |
| 4 | Exit from Holdover MTIE | | | 5 | nsec | |
| 5 | Holdover Accuracy | | | 50 | ppb | |
| 6 | Phase gain in the passband | | | 0.1 | dB | |

Note) Lock time of 1 sec is achieved when pulling a 9.2ppm reference for any selected bandwidth except 30 mHz and when phase slope limit is larger than 7.5usec.

Table 10 - DPLL Characteristics

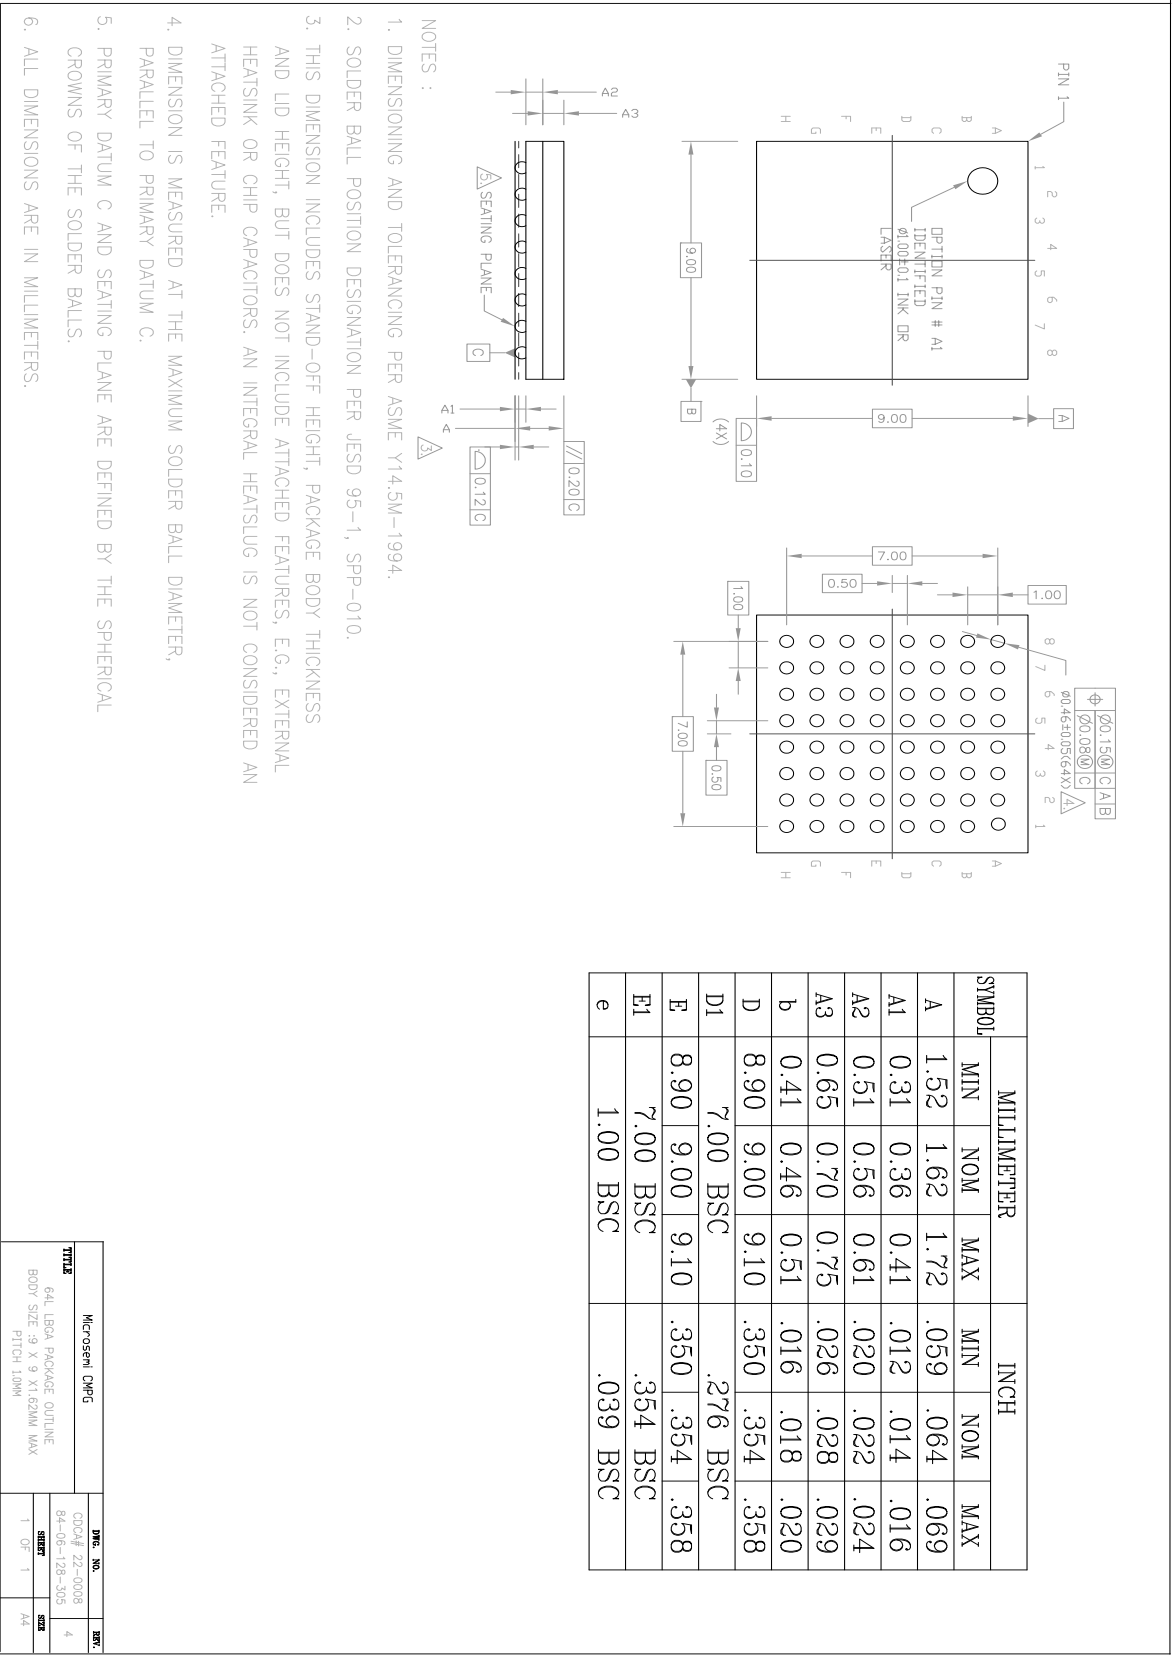

11.0 Thermal Characteristics

| Parameter | Symbol | Test Condition | Value | Unit |
|--|---------------|-----------------------------|----------------------|------|
| Junction to Ambient Thermal Resistance | θ_{ja} | Still Air 1 m/s 2 m/s | 35.5 31.9 30.6 | °C/W |
| Junction to Case Thermal Resistance | θ_{jc} | | 8.3 | °C/W |
| Maximum Junction Temperature ^{note} | T_{jmax} | | 125 | °C |
| Maximum Ambient Temperature | T_A | | 85 | °C |

Note) Proper thermal management must be practiced to ensure that T_{jmax} is not exceeded.

Microsemi Corporation (Nasdaq: MSCC) offers a comprehensive portfolio of semiconductor and system solutions for communications, defense & security, aerospace and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; security technologies and scalable anti-tamper products; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, Calif., and has approximately 3,400 employees globally. Learn more at www.microsemi.com.

Microsemi makes no warranty, representation, or guarantee regarding the information contained herein or the suitability of its products and services for any particular purpose, nor does Microsemi assume any liability whatsoever arising out of the application or use of any product or circuit. The products sold hereunder and any other products sold by Microsemi have been subject to limited testing and should not be used in conjunction with mission-critical equipment or applications. Any performance specifications are believed to be reliable but are not verified, and Buyer must conduct and complete all performance and other testing of the products, alone and together with, or installed in, any end-products. Buyer shall not rely on any data and performance specifications or parameters provided by Microsemi. It is the Buyer's responsibility to independently determine suitability of any products and to test and verify the same. The information provided by Microsemi hereunder is provided "as is, where is" and with all faults, and the entire risk associated with such information is entirely with the Buyer.
