### Functional Description

The MC100ES6210 is designed for low skew clock distribution systems and supports clock frequencies up to 3 GHz. The device consists of two independent 1:5 clock fanout buffers. The input signal of each fanout buffer is distributed to five identical, differential ECL/PECL outputs. Both CLKA and CLKB inputs can be driven by ECL/PECL compatible signals.

If  $V_{BB}$  is connected to the CLKA or CLKB input and bypassed to GND by a 10 nF capacitor, the MC100ES6210 can be driven by single-ended ECL/PECL signals utilizing the  $V_{BB}$  bias voltage output.

In order to meet the tight skew specification of the device, both outputs of a differential output pair should be terminated, even if only one output is used. In the case where not all ten outputs are used, the output pairs on the same package side as the parts being used on that side should be terminated.

The MC100ES6210 can be operated from a single 3.3 V or 2.5 V supply. As most other ECL compatible devices, the MC100ES6210 supports positive (PECL) and negative (ECL) supplies. The is function and pin compatible to the MC100EP210.

2. Operating junction temperature impacts device life time. Maximum continuous operating junction temperature should be selected according to the application life time requirements (See application note AN1545 for more information). The device AC and DC parameters are specified up to 110°C junction temperature allowing the MC100ES6210 to be used in applications requiring industrial temperature range. It is recommended that users of the MC100ES6210 employ thermal modeling analysis to assist in applying the junction temperature specifications to their particular application.

1. AC characteristics are design targets and pending characterization.
2. AC characteristics apply for parallel output termination of  $50 \Omega$  to  $V_{TT}$ .
3.  $V_{PP}$  (AC) is the minimum differential ECL/PECL input voltage swing required to maintain AC characteristics including  $t_{PD}$  and device-to-device skew.
4.  $V_{CMR}$  (AC) is the crosspoint of the differential ECL/PECL input signal. Normal AC operation is obtained when the crosspoint is within the  $V_{CMR}$  (AC) range and the input swing lies within the  $V_{PP}$  (AC) specification. Violation of  $V_{CMR}$  (AC) or  $V_{PP}$  (AC) impacts the device propagation delay, device and part-to-part skew.
5. Output pulse skew is the absolute difference of the propagation delay times:  $|t_{PLH} - t_{PHL}|$ .
